HOW SEALED CANS ARE TESTED.—An ingenious system has been devised for testing sealed cans in which food supplies are packed, to determine whether they are air tight. This is a matter of importance alike to packers and consumers. To the one it saves money, loss from spoiled goods, and to the other the danger of inadvertently using canned goods that have been partially decomposed. Immediately after the cans have been sealed they are placed in an iron or steel vessel that can be hermetically closed. The vessel is then filled with air under strong pressure, and after a few minutes the compressed air is allowed to escape suddenly. If a can has been imperfectly closed it will be filled with air under pressure, and when the outside pressure is suddenly removed that which is inside the can, being unable to escape through minute apertures quickly enough, will exert a strong outward pressure and bulge one or both heads. The bulged cans can then be picked out from the whole lot and resealed.

TO CLEAN HAIR BRUSHES.—The best way in which to clean hair brushes is with spirits of ammonia, as its effect is immediate. No rubbing is required, and cold water can be used just as successfully as warm. Take a teaspoonful of ammonia to a quart of water, dip the hair part of the brush without wetting the ivory, and in a moment the grease is removed; then

rinse in cold water, shake well and dry in the air, but not in the sun. Soda and soap soften the bristles and invariably turn ivory yellow.

A FISHERMAN'S KNIFE.—An English cutler now makes what he calls a fisherman's knife, which weighs less than a pound, and is carried at the belt, yet contains a gaff, scissors, weighing scale up to twenty pounds, large and small blade, a screw driver and file, a long disgorger and file, a tin opener, a corkscrew, a gimlet, an eight inch measurer, tweezers and pricker.

WAX MATCHES ARE MADE IN THIS COUNTRY.—An item has been going the round of the papers, to the effect that no wax matches are made in this country. A New York correspondent of the *Inventor* has written that journal that the report is incorrect—that wax matches are made by a firm in New York city, and that the business is a profitable one.

A WASH FOR OLD PAINTED WOODWORK.—Two ounces of soda dissolved in a quart of hot water will make a ready and useful solution for cleaning old painted work preparatory to repainting. This mixture, in the above proportion, should be applied when warm, and the woodwork afterward washed with water to remove all traces of soda.

AN EXPENSIVE SPIRE.—The spire for St. Patrick's cathedral in New York will cost, according to the architect's computation, \$190,000. The lower part, or tower, will be octagonal in shape, and 67 feet high, with a base of 32 feet. In each of the eight sides will be a window. Rising from this tower will be the spire itself, also octagonal.

ANOTHER WOOD-FILLER.—A wood filling composition may be made of whiting, 6 ounces; japan one half pint; boiled linseed oil, one half pint; turpentine, one half pint; cornstarch one ounce. Mix well together, and apply to the wood. For walnut, add a little burned umber, or cherry, a little venetian red to the above mixture.

LATHE CEMENT.—Take eight ounces best orange shellac, half an ounce ultramarine blue; melt the shellac in a vessel set in water or sand bath, and when melted stir in the ultramarine blue thoroughly and let it cool until it can be taken out with the hands and drawn or rolled into sticks of convenient size.

A FINE EXPOSITION BUILDING.—Pittsburg, Pa., is about to erect a very imposing and a permanent exposition building. To make it perfectly safe against fire it will be constructed entirely of iron and glass and will cost \$200,000.

MICE AS FISHERS.—It is not generally known that mice will dive in water to collect and eat the spawn and eggs of fishes.

GOOD HEALTH.

First Indications of Consumption.

It is not as extensively known as it ought to be, says *Hall's Journal of Health*, that in the large majority of cases consumption begins with a slight cough in the morning on getting up. After a while it is perceived at night on going to bed; next there is an occasional coughing spell some time during the night; by this time there is a difficulty of breathing on any slightly unusual exercise, or in ascending a hill, and the patient expresses himself with some surprise: "Why, it never used to tire me so!" Next there is occasional coughing after a full meal, and sometimes "coughing up." Even before this person begins to feel weak, while there is an almost imperceptible thinning in flesh and a gradual diminution in weight—harassing cough, loose bowels, difficult breathing, swollen extremities, daily fever and miserable death. Miserable because it is tedious, painful and inevitable. How much it is to be wished that the symptoms of this hateful disease were more generally studied and understood, that it might be detected in its first insidious approaches and application be made at once for its arrest and total eradication, for certain it is that in very many instances it could be accomplished.

It must be remembered that cough is not an invariable attendant of consumption of the lungs, inasmuch as persons have died and on examination a large portion of the lungs was found to have decayed away, and yet these same persons were never noticed to have had a cough or observed it themselves, until within a few days of death. But such instances are rare, and an habitual cough on getting up and on going to bed may be safely set down as indicating consumption begun.

Cough, as just stated, is originally a curative process—the means which nature uses to rid the body of that which offends, of that which is foreign to the system and ought to be out of it; hence the folly of using medicine to keep down the cough, as all cough remedies sold in the shops merely do, without taking means at the same time for removing that state of things which makes cough necessary.

PNEUMONIA AND OZONE.—Dr. Draper, of the Meteorological Observatory at Central Park, New York City, has called attention to the fact that during the past eight years there has been an apparent connection between the death-rate from pneumonia in New York and the presence

of ozone in the atmosphere. The epidemic has been particularly fatal during the present year, and it is stated on good authority that the death-rate from this cause has exceeded that from cholera in 1854. It has not been determined whether the connection between the disease and the ozone in the air is simply a coincidence, or whether there are scientific reasons for their joint appearance.

We know as yet but little about either the cause of the disease or of the modified form of oxygen which we denominate as ozone. In pursuing an investigation to discover their true relation, should any be found, two cases are possible: either that the ozone, which in large quantities we know to be injurious to health, is the direct cause of the disease, or that the same atmospheric conditions which produce ozone are also favorable to the spread of pneumonia. We are inclined to believe that the connection is purely accidental, but of the two hypotheses, the latter seems the more tenable, though Dr. Draper has apparently given it no consideration.

Removing Hair and Freckles by Electricity.

The American Dermatological Association lately held its ninth annual meeting at Greenwich, Conn. Among the proceedings were remarks by various doctors who gave their experiences in removing hair from the face by electricity. Quite a large and important business is done in this line, especially among ladies. The only remedy is to kill the root of each hair, which must be done separately, by means of an electrical needle and battery.

Dr. Fox said: In the case of a young woman with a heavy beard, he has removed, by actual count, 8000 hairs. This process has required two or three years. Since then it had been necessary to remove only a few dozen hairs.

The President, Dr. Hardaway, had performed the operation of electrolysis for ten or twelve years, probably longer than any other member of the association. He used the irido-platinum needle, which had the advantage of being bent, and was not likely to pass through the follicle well. The moment the follicle was entered there was an escape of sebum. One case, that of a woman with heavy black beard, had been entirely relieved. Electrolysis with a fine needle afforded a method of getting rid of freckles. The plan was to dot the surface covered by the freckle with the needle.

Freckles.

The following ointment was recommended by Dr. Heitzman and others at the late Greenwich meeting of the American Dermatological Association, being an ointment recommended by Wertheim, of Vienna:

White precipitate, 1 drachm.
Substrate of b'south } each, 1 drachm.
Glycerine ointment, 1 ounce.

This was to be applied in a thin layer every other night, and in from four to six weeks the result would be found to be highly satisfactory.

SORE THROAT.—Everybody has a cure for this trouble, but simple remedies appear to be most effectual. Salt and water is used by many as a gargle, but a little alum and honey dissolved in sage tea is better. An application of cloths wrung out of hot water and applied to the neck, changing as often as they begin to cool, has the most potency for removing inflammation of anything we ever tried. It should be kept up for a number of hours; during the evening is usually the most convenient time for applying this remedy.

FOR KIDNEY TROUBLE.—EDITORS PRESS:—Take the leaves of the common fir or spruce tree, make a tea by steeping (not boiling) them in hot water some 20 or 30 minutes. Drink hot. It will relieve almost instantly, unless the trouble is of long standing, when it requires a longer time.—M. S., *Pope Valley, Napa Co., Cal.*

PROPORTIONATE VALUE OF RAILWAY ACCIDENTS.—A French statistic gives the following as the proportionate number of persons killed annually on the railways of the respective countries: France, one in every 2,000,000; England, one in every 5,250,000; Belgium, one in every 9,000,000; Prussia, one in every 21,500,000.

MEDICAL VALUE OF SMALL FRUITS.—The small seed fruits, such as blackberries, figs, raspberries, currants and strawberries, may be classed among the best foods and medicines. The sugar in them is nutritious, the acid is cooling and purifying, and the seeds are laxative.

HOT WATER IN SYNCOPE.—Writers in the *London Lancet* call attention to the great value of hot water applications to the head in cases of fainting or syncope. They say also that a prompt use of it, applied to the forehead with cloths, will very often avert such attacks.

MUSTARD PLASTER THAT WILL NOT BLISTER.—Few people know how to apply a mustard plaster so as not to blister the skin. If the mustard be mixed with the white of an egg, instead of water, the plaster will draw thoroughly without blistering the most delicate skin.

TOOTHACHE, caused by a cold in the facial nerves, may often be relieved by wringing a soft towel out of cold water and sprinkling it with strong vinegar. This should be laid on the face like a poultice, and will often be followed by a refreshing sleep.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

CLEAN UP.—Amador Ledger, Oct. 17: The first regular clean-up of the Amador Queen mill was made Saturday and Sunday. How it turned out we are unable to say, although it is reported that the result was satisfactory. The first clean-up was not expected to average high, as a great deal of dirt and refuse material was mixed with the quartz. Mr. Shugert started Monday morning for San Francisco, on business relating to the mine. The mill has been running from 15 to 20 stamps the past week. At the Moore mine sinking operations have been temporarily suspended until pumping machinery can be put in, the flow of water being too strong to control with a bucket. The ledge of pay ore is said to be four feet wide, and the presence of a strong body of water is regarded as a good indication. The Plymouth Consolidated Mining Company, it is almost needless to say, paid a dividend on the 5th inst. of 50 cents a share, aggregating \$50,000. With this dividend this property has paid the stockholders \$14.50 per share, in 29 dividends, aggregating \$750,000. The parties who are working the Kennedy mine, under agreement with the owners to purchase the said mine, in case it meets with expectations upon being worked, are as follows: Thomas Varney, E. Judson, M. W. Belshaw, John Taylor, John Barton, J. M. Shotwell, Dr. Thomas Boyson, George Goodman, J. S. Doe, John Curry, F. Reichling, F. F. Thomas, David McClure, Jr., Charles F. Doe. They bind themselves in the sum of \$20,000 not to allow any liens of any kind to be placed upon the property on account of any work done or material furnished to said mine while in their possession. An agreement to this effect has been placed on record. Work has been resumed on the St. Julian at Middle Bar. A contract has been let to J. R. Price and H. Tripp to extend the lower tunnel 300 feet, the price, we are informed, is \$3.40 per foot. Work on the contract was commenced this week.

Calaveras.

GLENCOE.—Calaveras Chronicle, Oct. 17: Mr. F. A. Hanks, our well known capitalist, is erecting large hoisting works which he intends putting in motion in the near future. James Sullivan has bought an interest in the mine known as the Charlotte, situated about a mile and a half from town. They have fair prospects for a good mine, and as soon as water can be obtained they will begin operations. They have 700 tons of ore on the dump that will average from ten to forty dollars a ton.

Inyo.

KEELER NOTES.—Cor. Inyo Independent, Oct. 19: Thomas Boland shipped fifty tons of ore from Cerro Gordo this week. W. C. Morrison shipped thirty tons from the same place. Ten tons of ore are being hauled from Cerro Gordo daily. Eight men are now employed at the soda works on Owens lake. A dwelling house and engine house are being erected. The roof of Eddy's mill in Snow's canyon was torn off during a late wind storm, and the run had to be delayed a week or two for repairs. Mr. Israel Luce, proprietor of large marble works in Sacramento, arrived at Keeler on Thursday. He brought with him two men, and will soon put a force of men at work on his marble quarry at Swansea. Some Mexicans have struck a rich body of ore near the Yellow Grade on the Cerro Gordo road. Mr. Fairman went up to Independence on Thursday, on his way to Carson, where he will have his mill for Panamint framed; he reports the road nearly completed.

DARWIN.—Fitzgerald has increased his force of men, and is taking out A. No. 1 ore. Jack Wilson has several men out at Lee district chloriding. The recent success of Jerry Fitzgerald out there kind of "lightens up the gloom," as it were. No idle miners in town now. Every man who knows how to hit a drill "and 'it un 'ard," have gone to work.

Monro.

MILL CREEK.—Cor. Bodie Free Press, Oct. 17: Messrs. Schmeck, Kirkpatrick & Co. are working on their placer claim at the head of the lake. This claim covers all the tailings that come down the creek from the Gorilla and May Lundy mines. Experienced placer miners say that if these tailings, a deposit of six years, is handled right, thousands of dollars can be realized. Monday afternoon the dam on the middle lake in Lake canyon, broke and caused some damage to Eshe's reduction works.

Nevada.

RICH QUARTZ.—Grass Valley Union, Oct. 19: Several pieces of rich gold-bearing quartz from the Crown Point mine were brought to town yesterday afternoon by Richard Gauthier, which attracted much attention. The gold was in compact and solid granular streaks running entirely through the rock, unmingled with sulphurets. The rock itself was of that lively character that a practical miner always likes to see, as it gives assurance of a good gold-bearing vein, and such the Crown Point is showing itself to be by every day's developments. This rich rock was taken out at a depth of 180 feet, and at a point where the ledge is six feet in width.

PRICHENIX.—Foothill Tidings, Oct. 19: Work is going on admirably at the Phoenix mine, under the direction of B. A. Penhall, superintendent. This mine has but recently been started up, having been bonded by a Grass Valley company, and the entire amount of stock, save perhaps a few shares, is held by our townspeople. The shaft is now down 240 feet, the bottom level being in 80 feet, south from the shaft, with an 18 inch ledge. The ledge is well defined, and has every indication of being permanent. The last crushing taken from this ledge yielded \$127 per load.

NORTH STAR.—Work is being vigorously pushed forward, and the ledge is looking as well as ever. The shaft is still going down on the main incline, and soon the 1400 foot level will be run. It is expected that the company will strike a richer chute of ore in this level than they have in any other portion of the mine. The 10-stamp mill is kept running night and day on ore from the mine. Several weeks ago a shipment was made of \$2800 for one week's run at the mill, of 10 stamps, not including the sulphurets, which amounted to \$500. Sunday last there was a shipment made of \$2600 for less than six days' run, 10-stamps, not including sulphurets. We are informed by the superintendent, David McKay, that the sulphurets are worth \$113 per ton. The mill is now running on tribute rock mostly, and it verages \$70 per load.

DAISY HILL.—Seven loads of rock just crushed at Rogers' mill and taken from the Daisy Hill ledge, on south Auburn street, yielded 110 ounces, or nearly \$2000 in gold. This was taken out by two men in six weeks time, and came from the depth of about 130 feet.

COMET.—This property has been bonded by Richard Jones and party for \$3,000. Riley's mill recently crushed seven loads of ore from the Comet, and it yielded \$35 per load.

LOVE TREE.—The prospects are still bright for this mine, which is being put in proper shape for a run.

COE MINE.—The old Coe mine, located on the Grass Valley and Nevada City road about one mile from town, will soon have work commenced upon it.

HORSE SHOE.—The 26-foot wheel at the Horse Shoe shaft is getting ready to begin pumping water. A contract will then be let for sinking the shaft 100 feet deeper.

MAGENTA.—The water is about pumped out in the Magenta, and in a short time a contract will be let to sink the shaft 200 feet deeper, making a total of 500 feet. Of the Idaho and Empire there is nothing to say unless we repeat the same old story that has been told for years. They are both working away, are sinking deeper and deeper, have good ore and are paying regular monthly dividends.

OUTSIDE OF TOWN.—E. W. Roberts, representing San Francisco and Oakland capitalists, has bonded the extensive mining property owned by L. F. Buck, and located between Moore's and Orleans Flat, about 22 miles above Nevada City. The ledge is a very large one and can be worked through the tunnel which will soon be timbered and completed. John Lawrence, of the Plaza Foundry at Nevada City, is busily engaged in building the entire iron work for the 10-stamp mill, which will be placed on the Buck property as soon as the casting, etc., are completed.

THE CROWN POINT MINE.—Grass Valley Union, Oct. 20: It has only been a short time since the Crown Point mine was brought to the particular notice of the public, and now beyond all doubt it is one of the best properties in Grass Valley district. The ledge was located as early as 1858, but very little work was done on the location at that time. In 1871 or 1872 the ledge was worked by the William Penn Company, and considerable money was expended at that time toward development. A shaft was sunk to the depth of 250 feet or more and quite an amount of rock was taken from the shaft and the western drift, but not paying the mine was abandoned and the machinery sold. The property is now owned by A. Gauthier, who has been untiring in his efforts to find the pay chute. Mr. Gauthier continued the westerly drift some distance, but failed to find anything very encouraging in that direction, when he started a drift eastward at a depth of 180 feet. At a distance of about 40 feet he came upon the ledge and pushed the drift to a distance of 100 feet or more, the ledge increasing in width and the ore becoming better as the drift was advanced.

Placer.

HOTALING.—Herald, Oct. 17: In shaft No. 2 at the iron mine, which has been sunk with the view of prospecting the extent of the iron deposit, good ore was struck last Tuesday. It lies several hundred feet easterly from the old shaft, and gives proof of an extensive ore body. The quantity of coal and ore on hand at the furnace bespeaks a big run out there when they start.

MICHIGAN BLUFF AND VICINITY.—Argus, Oct. 17: The ledge at Last Chance owned by Byrne & McCarthy is reported to be looking richer than ever. The owners have a force of men at work running a tunnel on the ledge to tap their gravel channel. When this is done they will work the quartz in good shape. The Ralston & Nougues ledge at Last Chance is looking better and better. The ledge has been tapped about 200 feet below the surface, by means of a tunnel, and some of the richest quartz rock ever seen in this section of country was brought to view. Last Chance is looking up, decidedly.

Shasta.

FRENCH GULCH MINING.—Republican Free Press, Oct. 17: Our correspondent from French Gulch writes that owing to the scarcity of water, milling facilities are not extraordinary. The Washington is running but three stamps, and the Niagara, on Deadwood, is turning out the usual amount of bullion. The Huntington mill, just erected on the Vermont works, is working satisfactory with very good returns. The mills of McDonald, Bros. & Franck and Watt & Co., still keep up their lick. Quite a number of the mines are producing good ore. On the French Gulch side the Scorpion is working eight men with satisfactory results. Tom Green keeps about the same, and Wheeler & Son have just built a new cabin at their mine. The Brunswick Company are getting some good ore. When water comes the chances for a good turn out of wealth is good. The shipment through W. F. & Co. for September was \$11,500. The hills are full of prospectors.

NOTES.—Shasta Democrat, Oct. 14: Last week another rich pocket was struck in Lowry's claim near Centerville. The new strike pans out hugely. About 40 tons of high-grade sulphurets from Coleman's mine at French Gulch are at the depot to be shipped below. Mr. Merethew & Co. will have their quartzmill at Lower Springs running shortly with considerable good ore out to start on. Tom Green was down from French Gulch yesterday and shipped to the mint 97 ounces of gold bullion, the result of a two-weeks' run. We are told by reliable authority that a custom quartz mill will be erected this fall on the river near Redding. Such an accommodation is badly needed and will pay well. Dick Abbot last week made two locations in Old Diggings for himself and Tom Green that have the ear-marks of being good property. Some of the ore assays over 900 per ton. J. O. Stewart writes us a note from Copper City in which he states that the reduction works on the Winthrop mine are running along nicely, and the company will be shipping bullion three or four times a month. The Brunswick mining and milling company recently struck a rich pay chute on the De

Bonne location, situated in French Gulch district, this county. Considerable of the ore from this discovery is estimated to be worth \$1000 per ton. Whitton & Bassett will start up the arastra on their Squaw creek mine in a few days. They propose to put up a small mill as soon as they are able. We also learn that Jack Conant is constructing an arastra on his mine in the same district. Everything is booming at Iron Mountain, and just now it is about the liveliest camp in the county. Men are employed in the mine getting out ore, on the mill, on roads, cutting wood and timber, etc. About 100 men we are told are employed at various kinds of work and there will probably be room for more as fast as developments are made. Superintendent Elsworth has his hands full and has the good will of all under him.

Sierra.

GOLD.—Alt. Messenger, Oct. 17: Bald Mountain Extension Company, Forest city, cleaned up for last week's work 154 ounces of gold. The various branches of the Yuoa at and around Downville are lower now than they have been for years. The Ruby Company have the channel more concentrated than ever before, and are doing well. The large pipe for the Cleveland quartz mine, at Nigger canyon, went up Thursday morning. The mill will be started in a short time. Jesse Carney has his mill at the head of Jim Crow canyon about ready to run.

Tuolumne.

DEVELOPING.—Tuolumne Independent, Oct. 17: Fred, Sutton is developing his San Guiseppe mine, near town. The shaft is down 70 feet, and the rock raised looks fine. About 70 tons are on the dump and is being ground in an arastra. He expects to work about 100 tons as a test of the ore. Water being short the arastra only runs half the complement of drags; but this disability will be removed upon the advent of the full rains. Messrs. Stucker and Gale have been taking it out rich lately on the Garrett claim, at Brown's Flat. It is said that they have taken out between \$2000 and \$3000. Mr. Richards will soon commence operations on his claim at Table Mountain. He will doubtless reap a rich harvest, as the claim is supposed to be among the best.

SOLD.—Hon. W. G. Long has, we learn, disposed of the Willetta quartz mine, located near Jacksonville, to parties in San Francisco. It is a valuable mine. The rock is of a low grade, but in immense body, and a large number of stamps can be run to advantage. It is one of those claims which will do for permanent investment, with sure and regular dividends. Tuolumne has many such, and the sooner they are developed and disposed of to those having the capital to properly operate them the better for this county.

TO START UP.—The Riverside mine will shortly start up. Mr. James Barron has charge of the operations. This mine has been tried and proved, and under Mr. Barron's competent and skillful supervision will, without doubt, be made to pay. Several mines, having good reputations in the immediate locality, are lying idle for want of capital. Men having capital to invest in mines would do well to give Tuolumne a call.

NEVADA.

Washoe District.

HALE & NORCROSS.—Enterprise, Oct. 17: The track floor of the main lateral drift on the 3100 level has been regulated to a uniform grade, the drift put in proper trim throughout, with ample drain boxes placed to take any flow of water that may be encountered through to the Combination pump. Three new crosscuts have been started west into the ore vein, No. 1 at the Chollar south line, No. 2, 90 feet north and No. 3, 40 feet south of the deep winze. The two first mentioned are in about 35 feet each, both in good vein quartz carrying small streaks and spots of ore, with increasing signs of stronger mineralization as further advancement is made. No. 3 is in only about 13 feet. It cut through two or three small veins or stringers of ore, and its face was stopped in a good vein of ore which gives high assays. This had to be done in order to get the other crosscuts in out of the way, so that the car could pass without interfering with the workmen. Work is resumed in it, or will be to-day. On the 3000 level the north lateral drift from the top chamber of the deep winze is steadily pushing along towards the Savage south line, which is now 100 feet distant. A crosscut west from this drift, about 50 feet back from its face will be commenced to-day. As the drift is skirting along the east side of the ore vein, this west crosscut should demonstrate something before long.

CHOLLAR.—Crosscut No. 1 on the 3100 level, started during the past week on the line between this and the Hale & Norcross mine, and being run jointly with that company, is now in 35 feet west from the main lateral drift. It is all in fine-looking solid vein quartz, carrying small streaks and spots of mineral. Nothing is being done at present in the face of the main west Combination drift or crosscut or the southwest branch drift. The pressure pipe for the new or duplicate section of the big hydraulic pump at the Combination shaft is all in place, complete, and the connection will be made to-day. This will complete the pump, doubling its present capacity, ready for effective action whenever required by any increase of water tapped in the deep explorations. Its importance in that respect can hardly be overestimated.

CON. CALIFORNIA AND VIRGINIA.—About 100 tons per day is the present yield from the 1750 level, being extracted on company account and shipped to the Michigan mill for reduction, giving an average assay of about \$17 per ton. Twenty thousand dollars worth of bullion was shipped on Wednesday. Some little work is being done in the Jones lease section between the 1300 and 1400 levels, preparing better facilities for ore extraction when increase of water in the Carson river shall furnish the requisite motive power to run the Eureka mill.

CROWN POINT.—Sufficient ore is being extracted from this mine and the Belcher to give the Mexican, Vivian and Santiago mills what their present limited capacity will allow them to crush, which, in the aggregate, amounts to 160 tons per day. The old upper workings of Crown Point still show large amounts of low-grade ore. That from the Belcher is of higher grade, and comes from the 1750 level, above the water surface.

YELLOW JACKET.—About 170 tons continues to be the daily yield from the 1300 level and above. There is a vast amount of low-grade ore in this mine,

and while regular extraction goes steadily along, keeping the Brunswick mill well supplied, considerable prospecting work is being done in the upper portion of the mine, and also on the 1700 level through the Crown Point and Kentuck, above the water level.

UNION CONSOLIDATED.—On the 500 level the crosscut west was advanced 25 feet during the week, making a total distance of 84 feet. Material in face vein porphyry and quartz of a very favorable nature. The crosscut east on this same level, 100 feet south of the Sierra Nevada line, is also in very promising vein material.

SIERRA NEVADA.—On the 520 level the crosscut west 1000 feet north of the shaft, was advanced 40 feet during the week, making a total length of 445 feet. The face is now in hard dry porphyry, and evidently nearing the west wall of the vein.

BEST & BELCHER.—Crosscut No. 2 west on the 1000 level, 100 feet south of the old Consolidated Virginia line, was advanced 45 feet during the week. It is now 331 feet in length. Material in face vein porphyry, clay and a little quartz.

OPHIR.—The main drift or crosscut west on the 400 level from the old Mexican shaft is being continued across the ore vein towards the west wall, preparatory to stopping upward for the extraction of the ore at that point.

ALTA.—The west drift on the 700 level is making better advancement, owing to the formation being not so hard as it has been heretofore. Less than 200 feet farther will carry it into the ore body for which it is running.

GOULD & CURRY.—On the 1000 level crosscut No. 1 west at the Savage line has been extended 45 feet making a total length of 500 feet. Material in face hard, dry vein porphyry, with an occasional streak of quartz.

ANDER.—The crosscuts west on the 175 and 375 levels still give a good showing of quartz carrying a small amount of mineral. The lower level gives good assays occasionally from small streaks and spots of ore.

MEXICAN.—The middle crosscut east is being steadily advanced. The face continues in a heavy clay and soft, wet porphyry formation, with streaks of quartz which give low assays.

JUSTICE.—Some little prospecting work is being done at the south end, and ore extraction will be more actively resumed as soon as the old Thompson mill is ready for regular work.

KENTUCK.—The old upper workings continue their regular yield of low-grade ore, keeping the Rock Point mill steadily running.

MONTE CRISTO.—The new shaft is now down 175 feet. Bottom in hard-blasting rock.

Cottonwood District.

NICKEL.—Cor. Silver State, Oct. 16: It is authentically reported that the greatest nickel property of this coast, and, in fact, the most extensive yet discovered, has been lately sold to New York capitalists. This property was discovered in 1830 by the Bell Brothers, in the range of mountains bordering on the great salt deserts in Churchill county. The London mine, which is beyond doubt the most wonderful of the group, is situated at the junction of Cottonwood and Bolivar canyons, and, as far as developed, has produced the richest nickel ore that has ever been found. This character of ore has but lately been brought to the notice of metallurgists, and has been subjected to the many trials that follow all new discoveries, and in fact has passed through the many ordeals that befall all ores of unknown worth. It has been prophesied by nearly all metallurgists that the metal could not be extracted from the ore without great expense, but this has been wholly set at rest by the working of several tons of ore by a process of Chas. Bell, who reduced the ore and extracted the metal at a cost of three cents per pound. He informs me that the different ores can be handled as easily and cheaply as lead carbonates, taking into consideration the intense heat required to melt the metal. Bell has certainly overcome the main obstacle in cost of producing nickel. It may be of interest to give the various character of ores that are found on this property, the most characteristic being a grade called "arseniate," which is found in well defined veins, in large quantities, carrying from 20 to 28 per cent metal, while a character called "arsenite," which runs in connection with the first named character, will grade from 45 to 64 per cent metal. There is another grade called "arsenio-sulphure," which lies in large bodies but the most extensive character is the "silicate," which lies in bodies over 150 feet wide. There was also included in the sale three other locations, which are considered equal in extent and richness to those described. From what has thus far been done upon the property, it is safe to say that the new company can produce all the nickel used in the world for the next 20 years, and it is understood that a complete plant will be put upon the property within the next 60 days, and the property put upon a paying basis, which will equal those of the Comstock in its palmist days. We have not learned the amount paid for the mines, but believe it to be very large, as \$150,000 was offered for them a year ago.

Eureka District.

AN ENCOURAGING SIGN.—Eureka Sentinel, Oct. 17: Quite a good deal of substantial work is being done in a great many what might be termed "small" mines of Eureka district, and at no previous time has there been so little said about it on the part of the miners, many of whom have heretofore wanted mentioned in the paper every little inch or two-inch streak of ore encountered in their properties. It is a cheering sign, this quiet settling down to work instead of sitting around the hotels or standing on the corners telling of the wonderful merits of this or that piece of property. People have apparently learned that no matter how good a piece of property may be, unless enough development work has been done upon it to prove the value, it is no good either to themselves or anyone else. Wealth undeveloped is as good as no wealth at all.

Jackson District.

ENCOURAGING.—Silver State, Oct. 13: Very encouraging reports are received from Jackson mining district, some forty or fifty miles northwest of this place. The Pennsylvania mine on which John Catlow is building a new mill is looking well. A Fleming who recently arrived there from Colorado, has discovered a lead which pays from the surface, and

quite a mining boom is looked for when the mill is completed and they commence shipping bullion.

Mount Hope District.

A DISTRICT OF POSSIBILITIES.—*Eureka Sentinel*, Oct. 13: Inasmuch as a number of practical mining men of Eureka district expressed from time to time a desire to see his group of mining properties at Mt. Hope, and inasmuch as he had some business there that required his personal attention, Hon. Thomas Wren, on Sunday last, procured a special train over the E. and P. road and invited in all some 25 miners and friends to take a trip there. Mt. Hope is distant from Eureka 24 miles, and in early days was known as McGarry district. It lies in a range of mountains about one mile from the railroad track, and from some of the mining properties being worked a most enchanting view of a broad expanse of valley and rugged mountain country can be had. The district was worked, in a way, some 12 years ago, when ore shipments were made to Palisade and afterwards to the Richmond furnaces, but from what can be seen now of those workings they were both impracticable and fruitless of what should have followed the large sums of money and the labor expended. The formation of the district is, in the main, porphyry, with some little limestone; also, white crystalline and dark grayish rocks. Most of the claims located belong to Mr. Wren individually, and in two or three of them work is being systematically and actively prosecuted, so that in the course of a few weeks it would not surprise us to hear of ore shipments again being resumed. In one of the mines, near the surface, a large body of sulphate of zinc has been discovered and penetrated several feet, and there being plenty of water close at hand for the purpose, there is no doubt but that it could be cheaply mined and leached. On three or four dumps are good-sized piles of ore, but as the quality is low grade the same would either have to be assayed or concentrated to pay for shipping and working and then a profit to the owner. All the ore mined, however, is not low grade. On one dump was a pile which, no doubt, will be shipped some time, as it is heavy in lead and assays well in the precious metals. Altogether the district makes a much more favorable showing than any of the party expected to see. In fact, it abounds in excellent prospects.

Osceola District.

THE MILL.—*Cor. White Pine News*, Oct. 10: Our five-stamp mill is keeping up its regular tick day and night. It cleaned up from 100 tons of ore from the Gilded Age mine on the 1st instant 96½ ounces of gold bullion, or about \$1700, which shows Osceola to be a bullion producing camp, and I firmly believe that in less than one year we will take the lead of any camp in Eastern Nevada in this particular. We have plenty of ore here and no discount on our bullion when it leaves the mill. A. R. Watson, the principal owner of the Gilded Age, worked the mine and is now reaping the golden fruit of his labor. He has a breast of ore in the mine 4½ feet wide, all pay rock. Part of the vein is picking ground, and five men take out more than are enough to keep the mill running. A new office and blacksmith shop have been erected at the mine. Charles Bussy and L. S. Scott are taking out paying ore from the Florida mine, which they own, of which they have a large body in sight. Pat Reiva is working the Red Monster and taking out good ore.

Pioche District.

BULLIONVILLE.—*Pioche Record*: The smelting company have commenced operations in earnest at Bullionville. They have some 30 men now at work, grading and laying the foundation for the Statefeldt furnace, which is going to be the largest of the kind on the coast. The foundation is to be of solid masonry—80 feet in length, 13 in width and five feet high. It will be a month yet before the bricklayer can get to work, and two more before the furnace can be completed. One hundred thousand more bricks will be required to complete the building, a contract for that amount having been given to Mr. Morris, of Salt Lake City. It is estimated that the entire cost of the leaching plant and furnace will reach \$75,000.

Secret Canyon District.

NOTES.—*Cor. Eureka Sentinel*, Oct. 14: B. C. Levy and Jim Allen have taken a six months' lease of the Scorpion mine, Page canyon, Secret canyon district. They start in with a fine prospect ahead and some ore to work on from the word go. Dick Merryman has made another new strike in the Content mine, Page canyon, about 25 feet from the locality of the ore he took out several weeks ago. The Water Jacket mine, Page canyon, is yielding good ore right along. The lessees have great faith in the property, and are about to commence a new shaft for the more convenient working of it. Levy and Allen have a fair prospect in Harmon's claim north of the Geddes, and have started a tunnel, which will tap the vein at a short distance, and from which thorough and cheap prospecting can be done. Messrs. Nelson and Anderson are shipping another lot of good ore from the Geddes mine, Secret canyon. They are doing well. The Geddes mine, Secret canyon, is looking well in every direction, and it is said that the company starts up again the mill can be kept running on better ore than formerly for an indefinite period. The Irish Imbassador mine, Secret canyon, is said to be yielding some good ore, but not in such quantities as the friends of the owner and lessees would like to see. The latter, however, are the right men for the place, and will not damage the former good reputation of the property.

Willow Creek District.

WILD DEER.—*Silver State*, Oct. 14: W. H. Long has received a letter from Willow creek, which says the Wild Deer mine is opening up splendidly. They have struck fine bodies of rich ore in the lower works as well as in the upper levels. J. T. Griffin, who arrived here yesterday, reports that a gold bearing vein was discovered a few days ago not far from the Wild Deer, which seems to be as rich as the Oro Fino at Silver City. He brought down a specimen which is literally covered with gold from the new lead.

ARIZONA.

ARASTRAS.—*Prescott Courier*, Oct. 17: John Hutchins, an irrepressible miner, was here Saturday last, from Groom creek district, and seemed pleased to state that Mr. Rupert & Son are working hard to get their arastras going. They have some promising gold rock to crush. Capt. Spann, of Turkey creek district will, ere long, start one of his mills. Mr.

Ross returned here a few days ago from viewing the "Morgan's Kid" and other mines in Turkey creek district. He believes the owners of the Kid will have the silver extracted from the ore at the Tuscon-bia mill, which is now working fine ore for Messrs. Roach & Mulvenon. Major Houston tells us that the dam for retaining water on the upper canyon of the Hassayampa was completed on Saturday last at noon, by the Oro Fino Placer Mining Co. The cubical contents of the rock and concrete are 200 feet. Relatively, however, it is the smallest dam ever constructed on the coast for retaining the large quantity of water that is actually confined behind it, the conformation of the canyon above the dam being such that half a million gallons of water is retained before any passes over the waste gate. The company is now putting in flume work in the canyon.

DE NOON.—*Arizona Silver Belt*, Oct. 17: Mr. A. G. Pendleton, deputy U. S. mineral surveyor, has returned from De Noon, having just completed the surveys of the Woodpecker and West Side mines, which he says are excellent properties. The ledge is large, the outcrop being from 20 to 40 feet wide, the ore exceptionally rich; the character being chlorides, malleable silver and argentiferous galena. The vein is a contact between slate and porphyry. The country rock is slate. Sufficient development work has been done to prove the true character of the ledge; one shaft having been sunk to the depth of 80 feet with a good showing of fine grade ore. There is also a 40-foot cut showing 7 feet of free milling ore; at this place the walls are 20 feet apart. Taking the size of the ledge, quality of ore and amount in sight, the Woodpecker has few equals. He believes De Noon is the coming camp, in fact another Tombstone. The Woodpecker is on the same ledge as the Continental group, better known as the Keymer mines, and which have been incorporated in San Francisco. The Keymer is a splendid property. On one of these claims there is a continuous unbroken body of rich ore from the surface to the bottom of the shaft, a depth of 105 feet. There are many other promising properties in the district. A great mining camp at De Noon cannot fail to be a benefit to the entire territory.

A BIG LEDGE.—*Cor. Prescott Courier*, Oct. 16: Standing upon a knoll to the left of Antelope creek, a mile and a half below Stanton's, and looking to the north, I first saw the Veta Madre, the mother section of this section. Running easterly and westerly over the low foothills, losing itself in the mesa at one end and in the higher hills at the other, the mighty reef crested the bright and undulating ground with its bright and sparkling quartz. Walking over to the hill, where the croppings were most prominent, I found the whole summit and northern slope to consist of this huge mass of quartz, the apparent size of the true ledge being greatly increased by its dip to the north. The portion I was on I found to be the patented claim of Mr. E. P. Stanton, and in a tunnel and several cuts run in the vein by him, a better opportunity for judging its true size and character was given than the upper croppings could afford. In this tunnel, a cross-cut, the vein is seen to be split in three sections. The first is about eighteen inches across. Three or four feet of country rock (porphyry) intervene. Then another section of ten or more feet occurs. This is separated by another layer of country rock from the main body of the vein in which the tunnel stops. The total width of the three layers is probably not less than thirty feet, a truly gigantic size for a vein that affords, as I learn from several sources, from fifteen to twenty dollars in free milling gold per ton. Eight inches of gouge lie between the vein and its walls, and several feet of placer gravel cap the vein at the mouth of the tunnel. A large quantity of ore lies at the openings of the cuttings. This is seamed, mottled, oxidized and often honeycombed, and carries traces of copper. Many rich pockets have been discovered in the vein and many hundreds of tons have been profitably extracted. Dennis May, a well known and respected miner in this section, was, with Stanton, an original locator on the ledge, in 1872. Sexton, who then owned the Vulture mine, bought May out for \$10,000, and Stanton afterwards acquired it from Sexton. This vein, though lost to sight after reaching Antelope creek, passes through Rich Hill, and is found again at the head of Weaver creek, where Mr. William Johnson has been working it for many years. Mr. Johnson is one of the many remarkable instances that Arizona affords of untrifling belief in and devotion to a mining career. He has had, moreover, the exceptional good judgment to concentrate his efforts, the result being that his undivided work has opened up a mine in the real sense of the word. Many thousand feet of tunnels, drifts and shafts have developed a tremendous body of ore, low grade, but in a quantity that suggests a bonanza chamber of the Comstock or Silver King. Two adjacent properties, belonging to Mr. Johnson, are rich in gold, and enable him, with his two assistants, to live an independent and comfortable, though solitary life. It is believed by many that this great ledge, generally known as the old Sexton ledge, has, during its many years of disintegration, supplied the whole country round with the gold that is so profusely scattered in its ravines and mesas.

COLORADO.

GOLD AND SILVER KING.—*Georgetown Courier*, Oct. 14: Downie & Newkirk have let a contract to drive the tunnel on this Dumont property. They intend working the property steadily.

ALIUNDE.—The work of sinking the shaft goes steadily forward. Mr. Turck expects to continue active operations all winter.

MENDOTA.—Machinery has been placed over the Shay shaft, which is 200 feet deep, and a contract let to sink it an additional 150 feet, to make connection with the Victoria tunnel. Every working on the mine is in pay.

BALTIMORE.—The property is looking exceedingly well, and continues to output as usual. Several fine streaks of high grade ore are opened on the fifth level.

BISMARCK.—Four parties of lessees are at work on as many streaks of good grade ore, and the 15 men engaged are making over \$4 per day each, notwithstanding the low price of silver. Several millruns from this property were made this week.

STANTON MILL.—The test-runs made by the Stanton Engineering Co. on concentrating ores from several of our mines have convinced the stockholders that the Golden Gate concentrators are the machines for this vicinity at least. The company accordingly

decided last week to fit up the mill for winter work, and to substitute a new 100-ton crushing plant in place of the old stamps, which have proved inadequate.

SEVEN-THIRTY.—The first three days of this month there were shipped from the Seven-Thirty mine to Idaho Springs, 21 tons of ore that averaged over \$200 per ton, after deducting freight and smelting charges; the lot realized nearly \$5000. This ore was from various parts of the mine—the extreme east and west workings being at the present time large producers. Two men in drifting on the 80-foot level east took out ten tons of ore in two weeks. This ore was sold at Idaho Springs on the 3d inst. for \$1523.95, or at the rate of \$380 per week per man. Pretty good pay. A notable characteristic of mining in Clear Creek county during the past year has been the renewed work on long abandoned properties. Many mines that had become fossilized, as it were, have been re-opened, and are now yielding their quota of mineral. This has not been confined to particular districts, but is more noticeable in the sections immediate to Georgetown. In most instances where parties have resumed work on lodes having lain idle for years, the efforts have proven profitable, and the benefits will continue to be felt by the yield in the future. This fact gives evidence of a more stable condition of the mining industry. Democrat mountain mines are holding their own in point of production with other localities in this vicinity. Dumont people contemplate organizing a co-operative mining company to develop the properties in that neighborhood. During the month of September nine cars of ore were shipped from Silver Plume, one going to Denver and five going to Idaho Springs. The remainder was concentrating ore for the Stanton mill in Georgetown.

IDAHO.

ATLANTA.—News comes from Atlanta that the Atlanta Company has concluded to close down its mine and mill for the winter, and that Colonel Pettit, the superintendent, will leave in a few days for Hailey, on his way East to spend the winter. Owing to the pending negotiations for the sale of the Tahoma and Buffalo mine and mill companies' properties to English companies, very little work has been done on those properties this summer, and none whatever will be done upon them this winter—so that the only companies working in Atlanta this winter will be the Jessie Benton and Atlanta Hill, or Last Chance. The former will employ four or five men, and the latter eight to twelve. The total steady working force of Atlanta the coming winter will therefore scarcely exceed 25 men. The outlook for the town the coming winter is therefore worse than for years. Next spring, however, if the sales under way are accomplished, the place will be livelier than before.

THE RED ELEPHANT GROUP.—The last month's yield of first-class ore of the Red Elephant group of mines at Bullion, was marketed in this city yesterday. It consisted of 15½ tons, which, after deducting \$43 per ton for freight, sampling, reduction and hauling to the sampler, yielded an average of \$18.86½ net per ton, or a total of \$1780. The ore carried 123 ounces silver and the usual high percentage of lead. Even on this small shipment the effect of the discount on silver is very noticeable. If silver had been up to the average rate of the past few years, to wit, 113 per ounce, the Red Elephant ore would have brought \$12.30 more per ton, or \$190.65 additional for the 15½ tons.

MORE STAMPS FOR THE GOLD BELT.—Wood River Times, Oct. 17: The tappers, cams, shoes, dies, mortars, etc., for the ten additional stamps of the Camas No. 2 mill came in to-day, and will be hauled out to-morrow by Lufkin's teams to the Gold Belt where the battery blocks are already in place. The new stamps will be ready to start up in two weeks probably.

THE RECENT DISCOVERY.—The recent discovery in Bullwhacker gulch, Deer creek, of a mineral-bearing ridge has again demonstrated the truth of the saying that this region of country has scarcely begun to be prospected. Prospectors and pleasure-seekers have been riding all over the hills in the vicinity of Bolton's Springs, in every direction for years, suspecting, probably, that vast wealth lay beneath them, but unable to find it. At last, two painstaking men begin a systematic prospecting. They pick up a small piece of float, trace it up to whence it came, near the top of the hill, and get to an unpromising boulder, or succession of boulders, coated with white lime. One of these is broken, and behold! glittering galena—the purest kind of "truck"—is seen. A few blows of the pick, and 18 inches of high grade ore is found in place. A location is made, Abbie by name, and the work of uncovering the ledge proceeds with the gratifying sight, within four days, of a vein carrying ore of the thickness stated for a length of 60 feet or more. This discovery naturally caused some excitement, and the hills in Panther, Narrow Gauge and Bullwhacker gulches have since been alive with prospectors. At least a dozen new locations have been made, all of which are very promising, and two of which show a vein of solid galena. Messrs. Sulton and Mahoney intend to try to dig the bottom out of their mine at once, as they do not see any use of trying to put it on dress parade for moneyed men to see. So they have gone right to work, and will endeavor to begin shipping in a few days. So will Mr. Metcalf and his associates; they have a seam of ore, and they will take that out while looking for more. If this discovery holds out as expected, there will be a lively camp at Bolton's Springs next summer, as fully 200 miners will be at work within a radius of five miles.

KETCHUM NOTES.—*Keystone*, Oct. 15: Schad, Grenau & Willard will work the Tiptoe all winter. The Senate company is putting air pipes in its mines at Galena. The Ceresus on Smoky has ceased to ship ore for the winter. It is rumored that work will soon be resumed on the Buzzo group. Among Boulder mines to be worked all winter are the Ophir, Yankee Blade, Belcher and Tiptoe. A new body of ore has been discovered on the Ophir ground. It is five inches of black sulphurets. A great majority of miners at work on the Ramshorn, Postboy and Excelsior were discharged on the 3d instant. J. O. Swift was up Tuesday, attending to matters relative to closing down the Homestake mine and mill. They were closed down for the winter. In addition to the regular monthly bullion shipments from this point, the Vienoa mill and the Custer mill ship bar silver and the Fisher mill gold. Bassett Bros., who re-

cently leased the Star of the Mountain mine of I. J. Lewis, have struck ore and extracted from six to eight tons for shipment, with more in sight. The Rayhorse Smelting Co., it is currently reported, will build a stamp mill to replace their furnaces. A trial lot of their ore at the Custer mill convinced them that the dry process is the best. They lack sufficient lead for smelting. The new works will be built in the spring about two miles up the creek from Rayhorse.

MONTANA.

HELENA DISTRICT.—*Independent*, Oct. 17: The developments so far in this district are very encouraging, and the idea that has heretofore prevailed in Montana in regard to slate formation being no good for mines bids fair to be utterly exploded.

NEW MEXICO.

MAGDALENA.—*Socorro Bulletin*, Oct. 17: The Juana is working and shipping ore. Roseboom is steadily developing his Magdalena claims. Gen. Strickler is shipping ore from Bailey & Ryan's bonanza in Hop canyon. The Graphic is working full night and day shifts, which will be increased in a short time. Wythe Walker is working the Silver Bell, and proposes to ship one carload per week of good grade mineral, commencing in a few days. G. W. Parker, superintendent of the Anchor mine, is in the city. He reports the 150-foot contract in that property has been completed. It presents a very encouraging appearance. The Right Hand Beaver, Left Hand Beaver and Alamosa are undergoing the throes of development. The group is owned by E. Van Patten, and displays large bodies of galena and carbonate ore. The Kelly mine continues to yield sufficient ore daily to run the 180-ton Billing works of this city. The Graphic Mining and Smelting Co. of this city blew in one of its stacks Wednesday night. Mr. W. A. Konegan is the general manager; Professor W. J. Kohler metallurgist.

MISCELLANEOUS.—The Merritt mine is working increased shifts. The Las Vegas and St. L. M. & S. Co. are working steadily in Water canyon. The Carnero and Pajaro are both in full process of exploitation, and are delivering ore to the Brittenstone M. & M. Co.'s mill. The Brittenstone Mining and Milling Co. are showing the greatest diligence in placing their mill in operation. They fired up successfully on Wednesday last. The main shaft in the Silver Glimpse has attained a depth of 235 feet, and work progresses steadily. At that depth a vein of argentiferous galena in crystallized quartz has been encountered. The Santa Teresa, Induigan and other claims in the Socorro district, owned by Hon. F. A. Manzanarres and Don Abeyta Montoya, are showing up increased volume of ore under recent developments.

OREGON.

WINTER OPERATIONS.—*Jacksonville Times*, Oct. 17: Miners are making extensive preparations for next winter's run. Jack Layton has finished cleaning up and is getting ready for winter. Robt. Morris of Louise creek has a good mine which he will operate next season. J. W. Baker has purchased Robt. H. Dean's interest in the Willow Springs mines. A quantity of ore has been sent to Chicks & Co.'s mill in Siskiyou county, Cal., for testing. J. J. Brown is engaged in getting Wm. Bybee's claim on Rogue river in shipshape for winter. A number of prospectors are out looking for quartz ledges in the mountains south and west of Ashland. Henry D. Kubli, who was over from Applegate this year, reports considerable prospecting going on in that section. Sargent Bros. are doing well on Brush creek, in the Steamboat district. They will mine on a more extensive scale than ever next winter. A meeting was held at the town hall this week to consider Geo. H. Chick's proposition to put his mill here. No definite arrangements were made, but maybe hereafter. John O'Brien has bought several hundred feet of hydraulic pipe of Hays & Magruder, which he intends using in the Steamboat district. He has men employed in cleaning out his old ditch. Kinney & Lind have several tons of ore on their dump in the Evans Creek district which is very promising. Their claims continue to improve as work progresses. There are several other good ledges in the same region. The project of putting up a quartz mill at Medford has been abandoned, and Mr. Chicks proposes putting it up in this vicinity, if he can get enough inducements. A mill would be of vast benefit to Jacksonville in more ways than one. Marshal Curtis, who went to Josephine county last week on a prospecting tour, has returned. He informs us that he located a promising placer mine on Fall creek, a tributary of Jump-off-Joe, and has men engaged in thoroughly prospecting it. What this section needs more than anything else is a first-class quartz mill to work the ores of the ledges already discovered, many of which will pay well. Everything possible should be done to get one, for there is no calculating the benefit it will be. There is no doubt but what we have good quartz in Jackson and Josephine counties; but we must prove it before we can expect any amount of foreign capital to be invested here.

UTAH.

THE CHRISTY COMPANY.—*Southern Utah Times*, Oct. 10: Work is being pushed rapidly in the New Shaft, and the mine will be put in working condition as soon as possible. There has been several hundred tons of ore piled up on the California dump since the mill shut down. Within the past week an important strike was made in this mine. In running the drift north on the ledge, from the winze below the fifth level, the ore streak opened out to a width of five feet, a sample of which assayed 141 ounces per ton. The drift that cuts this ore body is 117 feet lower than the deepest working on the Buckeye Reef, and speaks well for the permanency of the Silver Reef mines. The Stormont Company produced \$18,300 worth of silver bullion last month. The mill crushed an average of 40 tons per day last week; the Savage & Buckeye furnishing 37 tons per day, while the balance was custom ore. The following shipments of ore were made to the River mill last week, by chlorides: Couch & Knowlton, 10 tons of ore from the Thompson; Ed. Lochney, 10 tons from the Bonanza; Smith & Jarmin, 10 tons from the old Lamb & Steele on the East Reef, the pulp assay of which was 76 ounces per ton.

MECHANICS' INSTITUTE INDUSTRIAL EXHIBITION

Of the City and County of San Francisco.

PREMIUMS AWARDED.

SAN FRANCISCO TOOL COMPANY

WERE AWARDED AT MECHANICS' FAIR, 1885,

GRAND SILVER MEDAL.....BEST DISPLAY OF TOOLS.
 SILVER MEDAL.....BEST ENGINE LATHE.
 SILVER MEDAL.....BEST DRILL PRESS.
 GRAND BRONZE MEDAL.....CENTRIFUGAL PUMP.
 BRONZE MEDAL.....HIGH SPEED ENGINE.
 BRONZE MEDAL.....BEST SHAPER.
 DIPLOMA.....BEST SHAFT COUPLING.
 DIPLOMA.....BEST CHECK AND FOOT VALVES.
 DIPLOMA.....SACK ELEVATOR.

AND AT SACRAMENTO STATE FAIR:

FIRST PREMIUM.....ENGINE AND PUMP COMBINED.
 FIRST PREMIUM.....TURBINE WATER WHEEL.
 SILVER MEDAL.....LOFTUS PATENT VALVE.
 SILVER MEDAL.....SINGLE-ACTING ENGINE.
 DIPLOMA.....SACK ELEVATOR.

CORRESPONDENCE SOLICITED.

GOLD QUARTZ and PLACER MINERS'

SILVER PLATED AMALGAMATING PLATES

FOR SAVING GOLD,

Have been Awarded the First Premium at Mechanics' Fair for the Last Thirteen Years.

Every description of plates for Quartz Mills and Wet or Dry Placer Amalgamator Machines made to order, corrugated or plain.

OVER 3,000 ORDERS FILLED!

References from every purchaser. Full weight of Silver guaranteed on every order.

The most extensive and successful manufacturer of these plates in the United States. Will fill orders for delivery in Rocky Mountain and Pacific Coast Mining States at lower prices than any other manufacturer.

Old Mining Plates Replated. Old Plates bought gold separated for low percentages of result.

SEND FOR PRICE LIST.

Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED 1860.

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enabled us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

Scientific Press

Patent Agency.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old
experienced, first-class Agency. We have able and trustworthy Associates and Agents in Wash-
ington and the capital cities of the principal nations of the world. In connection with our edi-
torial, scientific and Patent Law Library, and record of original cases in our office, we have
other advantages far beyond those which can be offered home inventors by other agencies. The
information accumulated through long and careful practice before the Office, and the frequent
examination of Patents already granted, for the purpose of determining the patentability of
inventions brought before us, enables us often to give advice which will save inventors the
expense of applying for Patents upon inventions which are not new. Circulars of advice sent
free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

 328,167.—PIPE WRENCH—R. E. Williams, Modesto, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

POUNDING AND WASHING MACHINE.—Wm. C. Nelson, Santa Rosa, No. 328,136. Dated Oct. 13, 1885. This device for pounding and washing clothes consists of a vessel open at the upper end, having elastic arms secured to each side and extending to some distance above the top, their upper ends inclining outwardly, and having flexible cords uniting and drawing them together, and a means for suspending the handle of a pounder centrally over the open top of the vessel, so that it may be forced down by hand to strike upon the contents of the vessel, and it will be raised by the elasticity of the arms. The pounder has also a number of perforations and a valve within it.

DOOR OPENING DEVICE. Julius Finck, S. F., assignor to Will & Finck, No. 328,114. Dated Oct. 13, 1885. This invention relates to that class of devices or mechanism used for operating doors from a distance, and it consists in a spring tending to open the door, and a spring tending to close it, both being preferably used in connection with a device for pushing back or releasing the door-latch. In many houses it is customary to provide means by which, when a summons is heard from the front door, the latch is released from a distant portion of the house; but it is obvious that the device is to a certain extent incomplete, from the fact that with many doors so svenly hung as to remain on the portion set, the mere pushing back of the latch will not notify the person outside that the door is ready to be opened. The object of the present invention is to produce a spring which will, when the latch is released, throw the door open; and as on many doors there are closing springs, it is necessary that the opening spring shall be of such a nature that, while performing its own functions, it will not interfere with that of the closing spring.

Mining Share Market.

While "indications" continue good at important points on the Comstock, the mining share market here languishes because the indications have so far led to no special rich development. The prospect on the 3100 level of the Hale & Norcross is considered of promise and merit. There is one there, but they want to find it more concentrated. The Virginia Enterprise in this connection says: "One thing is very evident, which is that the ore indications and actual developments in those lowest levels of the Comstock are far better than they have been for the last six months or more, and in fact fully as good as preceded the finding of the richly productive bonanzas of the Crown Point and Consolidated Virginia, at the south and north ends of the great lode. All who have lived through the the wonderful changes and booms of the past on this slope of old Mt Davidson will agree in saying that 'it is foolish for any one to say that because the rich ore indications have not thus far materialized or concentrated into a genuine old-time bonanza, there is nothing to be found in those lowest levels. The experience of the past teaches that there is no limit to the possibilities of the Comstock.'"

Bullion Shipments.

Germany, 13, \$9327; Utah, 13, \$2357; Hanauer, 13, \$9000; Stormont, 13, \$3150; Queen of the Hills, 13, \$3720; Honerline, 14, \$5153; Hanauer, 14, \$2900; Crescent, 14, \$3700; Vienna, 15, \$1890; Hanauer, 17, \$5615; Germany, 17, \$5216; Ontario, 17, \$29,507; Hanauer, 18, \$2710; Queen of the Hills, 18, \$1810; Blue Jacket, 13, \$6000; Lexington, 13, \$35,320; Alice, 13, \$17,600. The total silver bar shipments from Butte, M. T., for the week ending 17th aggregate over \$100,000. The Salt Lake ore and bullion output for last week was twenty-six cars, 624,542 pounds; thirty-seven cars ore, 994,320 pounds, and one car copper ore, 26,400 pounds.

POSITIVE fact! Muller is the leading optician, 135 Montgomery street, near Bush.

ASSESSMENT NOTICE.

Orleans Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Grass Valley, Nevada county, Cal. NOTICE is hereby given, that a meeting of the Directors, held on the 17th day of September, 1885, an Assessment (No. 12) of Five (5) Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, 934 and 936 Mission street, San Francisco, Cal. Any stock upon which this Assessment shall remain unpaid on the second day of November, 1885, will be delinquent, and advertised for sale in public auction; and unless payment is made before, will be sold on Monday the twenty-third day of November, 1885, to pay the Delinquent Assessment, together with costs of advertising and expenses of sale.

GEORGE P. THURSTON, Secretary.
 OFFICE—934 and 936 Mission St., San Francisco, Cal.

THE CELEBRATED

Woodbury Oils.

Pure, Perfect, Uniform!

The WOODBURY OILS are in use on the Central and Southern Pacific Railways, and on nearly every railroad and steamship line on the coast. We are not agents for other manufacturers, but have our own works, and adapt here all our Oils to the requirements of home machinery and our climate. We can show recommendations and records of tests, showing a saving to our customers of 50 per cent on their lubrication last year. Address

CHARLES J. WOODBURY,
 123 California St., San Francisco.

WORKS: Cor. Fifth and Townsend Sts.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

RANKIN, BRAYTON & CO.,
BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS,
embracing machinery of LATEST DESIGN and
MOST IMPROVED construction. We offer our cus-
tomers the BEST RESULTS OF 35 YEARS' EX-
PERIENCE in this SPECIAL LINE of work, and
are PREPARED to furnish from SAN FRAN-
CISCO or CHICAGO, the MOST APPROVED
character of MINING AND REDUCTION MA-
CHINERY, adapted to all grades of ores and SU-
PERIOR to that of any other make, at the LOWEST
POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DE-
LIVER in COMPLETE RUNNING ORDER,
in any locality, MILLS, CONCENTRATION
WORKS, WATER JACKET SMELTING
FURNACES, HOISTING WORKS, PUMP-
ING MACHINERY, ETC., ETC., of any DE-
SIRE CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD
ores of NEW and ORIGINAL DESIGNS, covered
by LETTERS PATENT. No other Furnace CAN
COMPARE with these for DURABILITY, and in
CAPACITY for uninterrupted work. MORE
THAN 150 of them are now RUNNING in various
parts of THIS COUNTRY, as well as many in
FOREIGN COUNTRIES, giving results NEVER
BEFORE ATTAINED as regards CONTINUOUS
running, ECONOMY of fuel, AMOUNT and QUAL-
ITY of BULLION produced. These CLAIMS have
been PROVEN BY RESULTS in ANY NUM-
BER of INSTANCES, and the GREAT SUPE-
RIORITY of this SYSTEM of smelting ores DE-
MONSTRATED BEYOND QUESTION. COM-
PLETE PLANTS furnished to order of any CA-
PACITY, with ALL IMPROVEMENTS that ex-
perience has DEMONSTRATED as VALUABLE
in this class of work.

Beyond question the cheapest and
most effective machine of the kind
now in use adapted to all grades and
classes of ores.

This machine has been THOROUGHLY TESTED
for the past TWO YEARS, under a GREAT VA-
RIETY of CONDITIONS, giving most EXTRA-
ORDINARY results FAR IN ADVANCE of
anything EVER BEFORE REALIZED. A re-
cent COMPETITIVE TEST at the Carlisle Mine in
Mexico, showed an ADVANTAGE OF OVER 30
PER CENT in favor of THE DUNCAN. The
amount SAVED OVER THE TRUE being suffi-
cient to PAY THE ENTIRE COST of the ma-
chines EVERY MONTH OF THE YEAR. One
of its MOST VALUABLE features is as an AMAL-
GAMATOR. It saves all THE AMALGAM GOLD
and SILVER that ESCAPES the BATTERIES,
PANS or SETTLERS, making the machine worth
MORE than ITS COST for THIS PURPOSE
ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist
and affording means for the continuous operation of a
Pump or Blower, without interfering with a hoisting ap-
paratus. It is made entirely of iron, no piece weighs
over 200 pounds. At the ordinary speed of a horse, a
1,000-pound bucket of ore may be raised 120 feet per
minute. The hoisting-drum is under the complete con-
trol of the man of the shaft, and is capable of carrying
500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS,
(\$575 00), F. O. B.**

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED

**PRICE, FIVE HUNDRED AND FIFTY DOLLARS
(\$550.00), F. O. B.**

THE "TRIUMPH" TRIUMPHANT!

**THE
"TRIUMPH" ORE CONCENTRATOR.**

In a competitive trial recently had between two of the "Triumph" Ore Concentrators and the same number of "Frue" Vanning Machines, at the mill of the celebrated gold producing Original Empire Mill and Mining Company, in Grass Valley, Nevada County, Cal., the "Triumphs" produced thirteen and fifteen one-hundredths (13.15) per cent more concentrations than did the "Frue" Vanners, during a run of twenty-four consecutive days, or a net gold coin result of \$199.15, or \$8.30 per day, in favor of the two "Triumph" Concentrators.

These returns do not include the value of the amalgam saved by the "Triumphs" during the test, which will add to the net gain. The form of construction of the feed bowl is such that considerable amalgam is necessarily saved, which is lost on the "Frue" Vanners.

This trial was conducted under the personal supervision of the Manager and Superintendent of that Company, in a strictly fair and impartial manner, and with the sole view of determining, in the interest of that Company, the merits and demerits of the respective machines by a thoroughly practical test. A relation of the course of procedure, a concise analysis of assays, and a tabulated statement of the net bullion results, with accurate deductions therefrom, will soon be published in Circular form.

The superiority of the present construction of the "Triumph" over the form originally introduced, together with the demonstrated results of the above, and other trials had with the "Frue" Vanners, induce us to and we hereby accept the Challenge of \$1,000, flouted by the Agents of the "Frue Vanning Machine Company," and hold ourselves in readiness to enter into a second competitive trial for that sum, at such place and upon such terms and conditions as may hereafter be mutually arranged.

We guarantee purchasers against all costs, expenses or charges incurred by reason of any infringements of any existing patents.

Number 18.

The Russell Furnace.

At West Point, Calaveras county, in this State, Mr. Russell, of the Russell Reduction and Mining Company, has erected a plant of about 10 tons capacity, which, we are informed, has been doing successful work. The roasting is done in a peculiar furnace, and after roasting the ores can be amalgamated in a pan or by chlorination. Some results of the work are given in the letter of a correspondent in another column in this number of the Press.

We give engravings of the Russell furnace on this page. In the furnace at West Point there are eight chambers, our drawing showing but five of them. The length is 50 feet, width 8 feet and height 6 feet. The inside diameter of each chamber is two feet one inch. The sectional view given shows the end of the chambers where they open into the heat passage.

The furnace was recently patented. It is peculiarly constructed with a number of chambers placed transversely across the heat passage. The ends of the chambers are open at each side of the furnace, as shown in the diagrams, with openings on top of the chamber to regulate the amount of oxygen for roasting ores. The ores in each chamber are heated by radiation, so that the gases from the burning fuel do not come in contact with the roasting ores. While these deleterious gases are excluded, the oxygen from the air is admitted from the outside. This gives complete control over the ores, and the length of time for roasting is shorter than in ordinary furnaces. The advantages claimed for the furnace are as follows:

1st. Base ores may be oxidized in this furnace that would slag in those of ordinary form, where the gases from the burning fuel come in direct contact with the ores while roasting.

2d. The combustion chamber, as shown, equalizes and stores heat, saves fuel, burns the gases from the fuel and also from the roasting ore. The gases are drawn off from the ores in the chambers as fast as said gases are evolved.

3d. The process of oxidizing bases goes on, with the gases being constantly drawn off (and none others admitted) until the bases are oxidized thoroughly and the precious metals are free to amalgamate, or chlorination may follow if preferred.

4th. In operating a furnace the workmen are free from the deleterious fumes of arsenic, sulphur, etc., etc., while attending to their duties in roasting.

5th. The roasting ores do not come in contact with the strong current of air in the heat passage from the fire, and the loss of fine gold or silver is very small.

At West Point, where the furnace is in operation, the ores are base. At or near the surface the gold was free, the sulphurets being decomposed; but on reaching the water level the ores became so hard to work that the mines were generally abandoned. Since this furnace was put up there has been a general revival in the district, so we are informed.

A DISPATCH from Fresno says: H. Dutertre, representing a syndicate of San Francisco mining capitalists, has concluded the purchase of a group of mines on the Harlow lode, in Mt. Raymond district, in the northern part of this county. The price paid was \$40,000. The mines are known as base metal, carrying silver and lead. The ore works as high as 67 ounces of silver and 30 per cent of lead per ton.

Mining Affairs in New Mexico.

We had a conversation this week with Mr. James A. Shedd, an assayer, from Santa Fe, New Mexico. He does not speak very encouragingly of mining affairs generally in the Territory, saying that the Mexican land grant system has been a great hindrance to prospecting. When he went to Santa Fe, three years ago, there were seven assayers. Now there are none, and what work of this kind is done is performed at the Brothers College. There is not much doing around Santa Fe. At Cerillos, 24 miles distant, there are many "gopher hole" claims that they ask a good price for. The Cash Entry is one of the few good mines. The ore in the region is very rebellious. Konemann has put up a large concentrator at the Cash Entry, and it is considered very successful. He has also

END VIEW OF RUSSELL FURNACE.

THE RUSSELL ROASTING FURNACE.

started a plant at Socorro, to which place he sends the concentrates.

There are not many new men coming into the country. Capital is badly needed. There is no use in prospecting on the land grants which cover so large an area, especially the "fraudulent grants." The people who own them keep others off. Lake Valley and Socorro are doing very well in mining matters. Around Santa Fe, however, the country is much broken up in the foothills, and there does not seem any certainty of finding continuations of the leads. Some assays Mr. Shedd has made have run high, but not very much of the rich ore was found. He has assayed very rich ore from Southern New Mexico, but there was no telling how much there was of it.

To illustrate how irregular the deposits are, he states that he tested ore brought in by a Mexican which was said to yield a white metal, presumably silver. On analysis it was found to be tin, and analyses made by others verified it. The percentage of tin was large. But the deposit petered right out when worked like others of the precious metals in that vicinity.

The first shipment of gold bullion from the Lapanta mine, near Hawthorne, was made to San Francisco last week. It was a little bar worth \$3,099.92. This is not bad for so new a discovery, and in fact, may safely be considered a pretty good starter.

Local Whaling Interests.

San Francisco is now one of the most important "whaling ports" in the United States. There has always been more or less whale-fishing carried on at the stations along the coast, the product of which was marketed in this city, and this port has been an outfitting station for some few whaling vessels. But in the past few years the whaling fleet which is outfitted here has grown very materially. A number of the vessels are now owned here, among them the steam-whalers, the best of the fleet. The Arctic Whaling Company have built large tanks for their oil on the bay shore, and the product is all handled here. The whalers that formerly outfitted at the Hawaiian Islands now come to this port. Oakland creek is now a favorite wintering place for the Arctic whaling fleet. Some of

Inaccuracies in Mining Surveys.

The case of St. Lawrence and Richmond Mining Companies vs. the Albion Con. M. Co., involving the right of the latter to proceed with its application for patent for the claim known as Albion No. 1, at Eureka, Nev., has been under consideration by the Secretary of the Interior. This application was filed as long ago as July, 1878, and stayed by the adverse claim of the St. Lawrence. Suit was duly commenced and is still pending. No adverse claim was filed by the Richmond, and its objection is based on a patent filed in May, 1881, alleging that the stakes to mark the claim, as surveyed, do not correctly bound the tract or the ground, but includes a small portion of the patented ground of the Tip-top mine, belonging to the Richmond Co.

The Land Office declared in April, 1883, that the protest was sufficient to authorize a hearing before the local office as to the fact of discrepancy; but later in the same month that ruling was modified and the protest dismissed, on the ground that further examination did not disclose a *prima facie* showing of conflict, and the allegation was not sufficiently clear to justify such order for hearing.

From this modified ruling the Richmond Company appealed to the Secretary of the Interior. In his decision he states that it is only necessary to suggest in disposing of this question, without deciding as to the status of the company as a proper contestant on such an issue, that it is a matter of ordinary administration relating to the question of possible error in the survey, and may be corrected by proper examination through the office of the Surveyor-General if any inaccuracy shall be discovered. In other words, the decision is to the effect that inaccuracies in surveys of mining claims may be investigated through the office of the Surveyor-General—not by a hearing.

MINERAL RESOURCES OF THE UNITED STATES. This valuable publication of the U. S. Geological Survey for 1883 and 1884—the report of the Division of Mining Statistics—has not yet been issued. The summary of production by statistics was given to the newspapers in June, and the entire report was stereotyped in August, but the Government printing office is evidently not to be hurried. These publications are not scattered broadcast among members of Congress, but may be purchased by any one desiring them. The price is 60 cents, which should be sent to the Director of the U. S. Geological Survey, at Washington, D. C. The last report, by Albert Williams, Jr., was one of the most useful Government publications ever issued, and this one will doubtless be even fuller of information concerning the mineral resources of the country. It is too bad that the publication is so long delayed.

MINING PATENTS.—Information has been received at the office of the Surveyor-General in this city that patents to the following mining claims in this State have been issued: No. 10,161, Columbus quartz lode claim; No. 10,162, Rochester quartz lode claim; No. 10,163, Aena ledge quartz claim; No. 10,187, Boudurant quartz lode claim.

ARTICLES have been filed incorporating the Portland Metallurgical Works, with a capital of \$30,000, to build and operate smelting works in that city.

the vessels leave here every fall to go to "the line" fishing and then work up to the Arctic when the ice breaks up, returning here with their cargoes. The high price of bone of late has made the business very profitable.

The bulk of the oil is re-shipped from here to the East, most of it going around Cape Horn in vessels. Of late, however, the railroad company has placed the freight rates at such a point that oil is shipped East by rail. One day last week the first shipment of whale oil for the season was sent from here. There were 17 carloads, or 460,000 pounds of oil. The train was a special one and it was intended to make the unusual time of 12 days to New Bedford, Mass., the destination of the consignment. No transfers were to be made. The whaling business of this port is now very important. There is a great deal of money invested in it. The steam whalers were some of them built here. The business is one which adds greatly to San Francisco's industrial importance.

CONSIDERABLE prospecting is being done on the west side of Mount Davidson. Float quartz carrying free gold is found in many places, and many locations have been made. Some of the rock exhibited is very good.

THE National Museum at the Smithsonian Institution, Washington, is overcrowded, and a new building is needed.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eps.

Hassayampa District.

EDITORS PRESS:—This district lies south of Prescott, in Yavapai county, and embraces the best wooded and watered portions of the Sierra Prieta ranges. The ores of this district are a free gold quartz on the surface which usually changes into sulphurets and a high percentage of silver as depth is reached.

This part of Yavapai county has produced more gold than all the rest of the Territory put together. The great richness of some of the deposits found here is something phenomenal.

Quantities of chlorides and sulphide ranging from \$5000 to \$25,000 per ton have been taken from this and adjoining district of Weaver, and ores assaying \$500 to \$1000 per ton are of common occurrence.

The rich placer mines of Governor Tritel, Secretary Van Arnam, "Old G. izleys," are in this district, and all have been successfully worked this year.

Over \$1,000,000 have been taken out of the gold mines of Weaver district, which bounds Hassayampa on the west, and the Marcus mine of Weaver is to-day being very profitably worked.

Montgomery Group.

Among the quartz mines of Hassayampa district, none have maintained a better reputation, if as good, than the Montgomery.

Discovered several years ago, by Chas. Genung and others, it was worked for four years under great disadvantages. Neither the Southern Pacific or Atlantic and Pacific railroads were built, and supplies had to be hauled about 200 miles. As high as \$1.75 cents per pound had to be paid for sugar, bacon, flour, and other materials for the mines in the same proportion.

The owners were poor men, and all the funds for development of the property were taken from this mine, which aggregated \$50,000. Owing to a disagreement among the owners of this property, work of important character was suspended until 18 months ago, when new owners took possession, and work since then has almost continuously been prosecuted.

There have been three extensions located, and work on each, as on the original mine clearly shows three distinct ledges.

One new 200-foot tunnel has been run in one of the ledges, the vein being from six inches to two feet, which reveal large bodies of ore that averages to assay \$200 to this ton, and careful assays on the entire ledge assays \$12.

There seems to be an almost inexhaustible quantity of free milling ore. Some estimate it at millions of tons of pay ore, and this property now bids fair to rival the Marens, Antelope Creek and Rich Hill of the Weaver district.

Besides a number of the territorial officers and of the army who had recently invested their means in the vicinity of the Montgomery mines, capitalists, through them, from Kansas and Ohio and New York have visited various properties within five to ten miles and invested in the Montgomery group.

A splendid belt of good pine lumber commences within one and a half miles of these mines and stretches for twelve miles north. A good road can, with but little expense, be built from this timber to the mines and the Hassayampa creek, where splendid mill sites are on the property.

Water for nearly eight months in the year can be secured in the creek for milling purposes, and if wells were dug for the entire year.

Work on other mines on the Hassayampa this season is showing good bodies of ore, shipments from which have been made to Pueblo, Colorado, and the returns are highly satisfactory to the owners. I will make reference to some of them in a future communication. G. W. I.

South Hassayampa, Sept. 20, 1885.

West Point, Calaveras County, Ores.

EDITORS PRESS:—During a recent visit to West Point I had occasion to examine some of the so-called "rebellious mines" of that district.

The district was discovered in early days by Mexican "Cambusinos," and worked by them in their peculiar style—steel bar, horn spoon, hatea and arastra being their implements for retracting and reducing the ore; and the burro or mule, their means of transportation. The English ton of 2000 pounds is unknown to them. The "carga" of 300 pounds makes a load. They assort their ore to \$10 the "carga," and 300 "cargas" make a "grind"; with the results the Mexican is happy until his money is gone. West Point was his happy, happy home, and he still remains—or what there is left of him—gray headed and gray headed, master of the situation.

To the average American this district has been and is a "terra incognita"—owing to the supposed difficulty of treating the ores and he has let it severely alone. The Mexican previous to his advent exhausted the free or decomposed ores for 30 feet in depth to the water level, the ores became sulphureted and "baso" and the

free gold coated, so that it would not easily amalgamate. So he, the American, hunted free ores.

The Metalliferous Domain

Of this district comprises an area of some 30 miles, and is composed of feldspathic granite, greenstone trap (diorite) and metamorphic slates. The veins are of quartz, and from three inches to four feet in width. They lie in groups of from 3 to 8, a short distance apart, and parallel with each other coursing N 15 W. The pay chutes are long but not continuous, as their dikes, varying from several inches to as many feet frequently cross the veins, but do not disturb, throw them or change the character of their mineral contents. They were evidently formed subsequent to the filling of the vein fissures. They serve as dams, and effectually bar the passage of the water, as a shaft can be sunk and pumped dry a few feet from a point where a dike crosses a vein, and water can be obtained by sinking on the other side, a few feet in depth. Each individual group, regardless of the formation, seems to be governed by a law of its own. In one, tellurides predominate as a base, another—grey copper ore (a fahlerz,) another—mispickel, (arseniferous) and another a simple sulphuret of iron, all, however, carrying an unusually large percentage of gold—seldom less than \$100 per ton, ranging to \$500 (the concentrated stuff). The sulphurets often occur massive with little or no gangue. During my examination of the mines referred to, I noted some points of marked interest to the miner, and will note them for his benefit.

My tests were taken in this usual way, from all parts of the mine in from 50 to 100 samples—53 in all, which I granulated and reduced by halving and quartering, etc., to three feet, two-thirds of which I pulverized—one-third for assay and one-third for horn spoon tests; one-third of granulated ore for a working test.

My results of one of the samples of a highly sulphureted ore from below the water level were as follows: The pulp when washed in a horn spoon yielded in free gold \$75 per ton. This I put in a horn spoon with quicksilver, and found that I could only amalgamate two-thirds of the remainder though bright, and to all appearances would not amalgamate. One-third ground in a pan and amalgamated yielded \$45. This fire assay value of this pulp was \$225 per ton.

I then took a portion of the same pulp and roasted it on a tile in the open air until I obtained a dead roast. My result washed in a horn spoon was \$196.50 per ton, but this gold would not amalgamate, or but a very small portion of it, showing that it was coated by some substance.

I related the circumstance to Mr. E. F. Russell, of the Russell furnace, whom I met at West Point. He said that he would like me to try his small portable furnace similar to the one he was using on a large scale at his works. I assented and he sent me one and some bricks. I soon had it in working order. I roasted a portion of the same pulp washed it in a horn and obtained at the rate of \$220 per ton, the gold with a slight tribulation in the spoon with quicksilver amalgamated instantly.

Many years of experience has taught me "to go slow" on new and untried processes, mills and patent inventions, but my experience with the Russell furnace on these ores has so much interested me that I would like to see it tested on a few hundred tons of "rebellious ore." Mr. Russell claims the furnace will work telluric ores with good results. If so he has solved a problem that will greatly benefit the gold mining interest in California, as many of our ores carry tellurides which hitherto has been a dead loss to the miner—the gold with the tellurium volatilizing with ordinary furnace.

I. H. CROSSMAN.

WATER RIGHTS AND CONTRACTORS.—A decision has been rendered in Department 2 of the Supreme Court, which involves a nice point of law in regard to water rights and the obligations of contractors in mining districts. In November, 1883, the Sierra Union Water and Mining Company brought suit against G. F. Baker in the Superior Court of Sierra county, to recover a judgment in \$16,000, claimed to be due for water supplied according to contract for that season. The contract was originally made between Morgan and Donahue and the defendant, and stipulated to carry the water of Trainor ditch and all its tributaries, together with the "tail water," from Table Rock township to Sawmill ravine, in Sierra county, for his use at the Pioneer mine, for \$16,000 a year. Morgan and Donahue subsequently transferred this part of the contract to the plaintiff, who failed to comply with its condition, and commenced suit on failure to collect the \$16,000 of the defendant. The plaintiff argued that it was not compelled by law to run the "tail water," of Table Rock township into Trainor ditch, as specifically set forth in the contract, so long as the natural bed of Trainor ditch was above the level of the "tail waters." The Court held that the letter of the contract must be obeyed, and rendered a judgment of \$800 and the costs of the suit in favor of the defendant. The Supreme Court has affirmed the judgment of the lower Court.

A LOAD OF ORE, in Grass Valley district, is about two tons minus two or three hundred pounds. The word ton ought to be adhered to by our miners and millmen. A "load" is too much like "the size of a lump of chalk."—*Foot-hill Tidings.*

Sulphurets and Sulphuret Sharps.

A correspondent of the Tuolumne Independent says: The great unknown quantity in gold quartz mines, is the value of the sulphurets, and the number of companies who have been ruined by them, is very large. They are often fair to look upon, but as often prove deceptive—

"Like Dead Sea fruits that tempt the eye,
But turn to ashes on the lips."

They are of many kinds and colors. Some are docile, some are rebellious. The sulphurets found in gold quartz mines are chemical compounds of sulphur, with iron, lead, zinc, copper, arsenic and antimony. The common pyrites, or sulphurets, are composed of iron and sulphur. Galena is composed of lead and sulphur. Zinc blende, or black jack, is zinc and sulphur, with a little iron and lead, generally. The brassy looking pyrites, which are technically called chalcopryite, are composed of iron, copper and sulphur; and, other kinds of sulphurets, are composed of one or more of the metals mentioned above, and sulphur.

When much lead, zinc, arsenic and antimony are present, the sulphurets are called base or refractory, and are very troublesome, requiring roasting, as a preliminary step, and the use of chemicals in the subsequent grinding processes. The gold which occurs in sulphurets, is held there mechanically, and is not chemically combined, like the other elements, and is held just the same as the gold in the quartz, with the exception that sulphuret gold is smaller and lighter. It can be set free from the pyritic matter containing it, either by dissolving the pyrites with acids, or, in the chlorination process, by chlorine gas, which dissolves the gold, or by roasting or burning them, thus driving off all the sulphur, arsenic, antimony or zinc, that may be present, and brightening the gold and leaving it in a good condition to amalgamate in pans or arastras; or, lastly, by grinding the sulphurets raw, in pans or arastras, with quicksilver. Which one of these processes any mine needs, has to be determined by the value per ton of the sulphurets, and by their docility or their rebelliousness.

Some mines produce sulphurets which yield their gold when worked raw, by a grinding process; others hold the gold closer, and require chemicals, or else roasting. The problem is, how to get the most net profit out of them; for, while the chemical processes yield a better percentage of the assay value per ton, they are so expensive that they will not pay as much profit as the cheaper processes, which do not yield as high a percentage of the assay value, and the tendency of the times is now toward the cheaper, or grinding processes. In cases where they are base, a preliminary roasting is necessary.

Pyrites, or sulphurets, are spotted, just as quartz is. Some are rich, some are poor, in the same ore, and no eye can tell rich from poor; and, any one who pretends to do so, either deceives himself, or is a humbug. "A man may smile and smile, and yet be a villain;" and so can the bright shining sulphurets be of no value, or the dark, gloomy ores be rich. The only way to test them is by fire assay, or by roasting them and panning out; and here is where many people are deceived, for they are inclined to think their sulphurets all alike, and if one chute or chimney of ore contains rich sulphurets, all their other chutes are likewise rich, which may or may not be the case, and it can be laid down as a rule, the sulphurets want as careful prospecting as the quartz, before any correct idea of their value can be found.

About as uncertain as the sulphurets themselves, and often as stubborn and rebellious, is the sulphuret sharp—the man who has a process or processes to get more gold out of sulphurets than is in them. He is a man with a hobby, and often with a crank, as well, and is always finding some wonderful process which turns out to be sound, proved, tried and everything but true or useful. Processes which look well on paper, or work well on a small scale, fail when tried commercially or practically. They are sound in theory, but ruinous when used practically. Every few years a new sharp finds the true process, and the mining world goes mad over the man who has found the great secret, but somehow or other he fizzles out, and we all go back to first principles, until another new sulphuret meteor flashes across our horizon, and then we all are agog with renewed excitement until he flashes out of sight again.

Simplicity and cheap handling of sulphurets is what we are tending to, and the simple processes, which do not yield as high a percentage of the assay value of the sulphurets, yield a better net profit to the miners than the costlier processes, which save a larger percentage of gold. The sooner the whole matter is robbed of the air of mystery that surrounds it the better. To hear one of these deeply, darkly mysterious sulphuret men talk, reminds one of the days of alchemy, and carries us back down the centuries, to the age of superstition—to the time of magic elixirs of life, and the philosopher's stone, and the humbuggery of the ancient magicians. Let us look at mining in the full daylight of modern science and practical business, and have no more humbug mystery, worthy only the dark ages and the childhood of mining. Let us return to the blanket-sluice for a concentrator, and work the blanket tailings in a pan or arastra, raw, if they are docile, or roast them, as a preliminary, if they are base, and be content with the result; for by

striving to get the last cent out of the sulphurets we lose rather than gain. The great army of concentrator and sulphuret sharps, who have afflicted this coast, have caused the loss of millions of dollars with their new-fangled plans and experiments, and want to be sent to pot to await the coming of their brothers—the mischievous, gay, deceiving patent quartz mill men—who are now reaping the harvest of the mining greenhorns, which the concentrator and sulphuret men used to look on as theirs. Ruin follows in the wake of all these mining humbogs, and almost every quartz mill, from San Diego to Alaska, shows some of the marks of these new processes and machines which generally get more gold out of the miner's pocket than out of the sulphurets.

THE BANKERS AND SILVER.—In terse and most expressive language the Chicago Current says: "The Chicago (bankers') convention was Belshazzar's feast." We believe that is true. A band of men who do not represent anything but the aggression and soullessness of aggregated capital, met there and prescribed rules through which the millions of producers in this country might be placed under perpetual tribute to them, and the interest-bearing debt of the nation might be made perpetual. So bungling, too, was they work, that their purpose shows plainly through the cracks in the structure which their upreared. The people will not accept their edicts for many reasons. They represented, intellectually, a low order of men. They treated their own theories as established facts, and supported them with false testimony. They indulged in prophecies which had no mors divinity in them than a Mormon elder. They tried to take advantage of their own wrongs to gain sympathy for their designs from the country. They painted pictures which left the impression that the five per cent of foreign trade which this country enjoys, is of more importance than the 95 per cent of domestic trade. They spoke from a position on the seashore with their eyes longingly straining toward foreign lands, with their backs turned to their own country and its real interests. The majority of them have no conception of the place which their country occupies among the nations, and a stranger, listening to them, would have thought that this Republic, if not confined to Wall street, was certainly indebted to Wall street for its license to do business. When that convention laid down its plan to cure existing evils by striking a death blow to the ruling industry of a great section of the country—an industry, by the way, more necessary than any other—they revealed plainly the fact that even if their motives were good they lacked the intelligence necessary to give their motives dignity or to command respect. We believe it will prove a Belshazzar's feast to them indeed, for the offense people read of their proceedings this more indignant their grow. We believe that when Congress meets the battle-cry will be, "Free coinage of silver," and "Precisely such laws governing silver as govern gold."—*Salt Lake Tribune.*

NEW GOLD SAVING MACHINE.—A newly-invented gold-washing machine is now being used at some of the placers along the Arkansas river, between Granite and Salida, which is said to produce phenomenal success. This machine is described as follows by the Denver Journal of Commerce: The machine is composed of three sections, about 8 feet in length, overlaying each other at the lower end, 16 inches wide and 10 inches in depth. There are three gratings, one at the end of each section, made of three-eighths inch half-round iron, beveled at almost a point at the top, and with 25 one-sixteenth inch openings in width, through which the water carries the sand into the pockets underneath and following the gratings. There are 12 pockets in each section, with openings or plugs, which allow the withdrawal of any or all of the different pockets. These pockets are of light sheet-iron, 15 inches long, placed almost on a level with the bottom of the section, with an opening of an inch or more, and the double flange that creates a rotating current of water, carrying off the surplus sand and leaving the gold within an inside pocket or at its bottom. The sand is carried by the water to the top of the next grate to the following 12 pockets of the second and third sections. The process is so perfect and the fine gold so surely saved that it is very seldom that they clean up the pockets of the last section. They claim that the first four or five pockets of the first section will save at least 90 per cent of the gold. The cleaning up is done by a miniature machine of the same description, containing six pockets, and without the use of quicksilver, it being placed within the flume at any point. The inventor of the above described machine is E. W. Stouffer, who, last spring, started a small assay office in Redding, in this State.

THE YUKON COUNTRY.—A dispatch from Victoria, B. C., says: The steamer Idaho arrived from Alaska to-day, and brings the following additional news: Frank Dunsinuir and Joe Hughes, Yukon prospectors, have arrived at Juneau from the Yukon country. They made down the Yukon river 600 miles and then up the Salmon river 425 miles to its headwaters. They found very good diggings on the bars. They left 20 men in that country who are going to remain all winter. Some are in Yukon, some on White river and some on the Salmon river. All are making from \$7 to \$8 a day to a man on the bars.

Silver or Gold.

"Advocates of the free and unlimited coinage of silver," says the *Denver Times*, "will find a strong argument in the table of statistics given below, which is taken from the report of the United States silver commission. The table gives the names and the populations of the countries which use the single silver, the double and the single gold standards. Here they are:

SILVER STANDARD.		Population.
Russia.....	4,500,000	76,000,000
Austria.....	3,600,000	36,000,000
Egypt.....	1,000,000	4,500,000
Mexico.....	2,000,000	8,000,000
Central America.....	2,000,000	2,000,000

Total.....		87,080,000

"These tables show conclusively," continues the *Times*, "the popularity of silver as a coin, and stand out strongly in support of the representation that silver is the money of the masses. The facts are worth studying. The aggregate population of the countries mentioned in the table is about one billion, of which fewer than 100,000 million, or less than one-tenth, use gold exclusively as money. Less than one-fifth use both gold and silver, while three-fourths use silver exclusively as their standard of value and medium of exchange. Furthermore, the figures plainly demonstrate the tendency of silver to crowd gold out of circulation, and especially is this true in the old and most densely populated countries. The three countries of largest population on the globe, China, India and Russia, are all represented in the list of countries which employ the silver standard. From this table there is a gradual tapering through the list to the gold standard table in which only two countries of considerable population are represented, these being Germany and Great Britain, with a combined population of 74,000,000 people. Even in these two countries small silver coins are used. The point of the whole exhibit is that silver is rapidly pushing to the front as the money of the people."

Con. California and Virginia.

On the first of November a year ago the two most famous bullion-producing mines on the Comstock, and in the United States—the California and Con. Virginia—were consolidated in one company, called the Consolidated California and Virginia. This consolidation was effected from motives of economy, in saving salaries of double sets of offices, etc. Most people have an idea that these mines are producing nothing at all, but they are mistaken. During the last 11 months—since the consolidation—\$610,463 have been produced from the ore extracted. Superintendent W. H. Patton reports to the President of the company that between Nov. 1, 1884 and Oct. 1, 1885, there have been extracted from the old 1200 and 1300 levels, under the terms of the Jones lease, 13,487,855 2000 tons of ore, all of which has been milled—yielding bullion of the assay value of \$310,109.69—of which \$134,939.12 was in gold and \$175,170.57 was in silver, being at the rate of \$16.77 per ton. According to the terms of the contract the Con. California and Virginia company has received, at the rate of 50 cents a ton, the sum of \$9,243.71 as royalty on the whole quantity of ore extracted and milled.

There have been extracted by the company itself on its own account during the same period of time from the 1750 level 20,442 tons of ore, of which 19,677 30 2000 tons have been milled, producing \$330,354.28 in bullion, of which \$223,995.78 was gold and \$106,358.50 silver, the average yield being \$16 78.8 per ton.

The northwest drift on the 1750 level in the California mine has been extended to a point 580 feet from the main west drift, reaching the old California north stopes. A large portion of the low-grade ore which has been extracted from the mine during the past year has come from these old stopes, this part of the mine having been drained and cooled off so as to enable them to carry on the work of extraction at a much less expense than in former times. In March last a drift was started from the main west drift in a southwesterly direction, and it has been extended to the old Consolidated Vir-

ginia south stopes. They here found, on cutting into the old workings, that fire and gas still existed, but by careful management some low-grade ore has been taken out from this part of the mine, and more may be extracted in the future.

In January last, in accordance with a resolution passed by the Board of Trustees, all work was suspended below the 2000 level, and the machinery and material were removed from the various drifts and winzes, and the pumping machinery on the surface was stopped. At this date, October 1st, the water is up to the 2000 level, and is rising at the rate of about two feet per week.

To show where the money comes from and where it goes to in running a big mine like this, the following statement of receipts and disbursements of the company from Nov. 1st, 1884, to Oct. 1st, 1885, are given:

Cash on hand brought from Consolidated Virginia Co's account.....	\$ 1,008 35
RECEIPTS.	
Salaries and wages.....	12,517 70
Mine supplies—	
Wood.....	\$ 513 00
Timber and lumber.....	14,470 37
Ice.....	217 25
Oils and lubricants.....	73 50
Candles.....	298 40
Powder, caps and fuse.....	74 75
Iron and hardware.....	1,796 65
Pipe and fittings.....	2,221 77
Drill fittings.....	626 51
Miscellaneous supplies.....	3,425 52
Transportation and hauling.....	23,426 72
Hoisting.....	209 00
Compressed air furnished to adjoining mines.....	167 20
Assay office expense.....	3,193 19
Assaying.....	1,016 10
Bullion melting.....	466 32
Net proceeds of bars of bullion from blue sweepings.....	1,037 50
Team expense.....	3,110 92
Office expense.....	622 17
Sutro tunnel royalty.....	1,505 30
Mine royalty.....	18,487 44
Superintendent's drafts Nos. 2 to 93, inclusive.....	9,243 71
	310,085 02
	\$385,067 78
DISBURSEMENTS.

Total.....	\$385,067 78

THE MINES OF NEVADA COUNTY.—Bodie, some six or eight years ago, was a town of 6000 inhabitants and it boomed. It had rich mines and the shares of its mines sold at the stock boards of San Francisco. Bodie has now a population of 500. This reminds us to say that Grass Valley, which is a mining town, has never gone back since the day it was founded. Grass Valley is not a county seat, but has had to depend on her own bottom. She was a quartz-mining town from the start, her gravel mining never amounting to anything. Mining excitement have sprung up all over the coast and mining cities have been built up which were larger and made much more fuss in the world than Grass Valley, but this town kept ahead slowly but surely, and has to-day a larger population than she ever had at any other day. And Grass Valley has the mines to keep the population and to increase. It is true that this place has fruits and trees, and can grow grasses and forage crops, and can have the best of garden truck grown right within her borders, yet without her mines she would only give occupation to some dozen or two of families. It is a still further illustration of the excellence of the mines of this region when it is a fact that four miles away there is another town almost as large as is Grass Valley, and that, too, depends mostly upon its quartz mines for permanency. That other town is Nevada City and it has the county seat business, which is some help to it, but the county business alone would not make it have necessarily more than 10 or 12 people. The two largest gold mining towns in the world are in Nevada county, California, and they are only four miles apart, and they are both growing and not decreasing. Yet both towns have growlers who are every day predicting that this part of the country is going right straight to the "demonition bow-wow."—*Foothill Tidings*.

SMALL MINES BUSY.—There has been more quiet, systematic development going on among mines, so far as number go, during this season than at any time in the history of Eureka county. While it is true that some of our largest and best properties have been—well, almost idle, the owners of small mines have been busy.—*Eureka Sentinel*.

Draining Wet Shafts.

Innumerable instances are on record in this district, says the *Leadville Herald*, of the errors made by mining men in attempting to drain wet shafts. Frequently when new shafts and workings or old mines are to be drained, a great flow of water is encountered and the pumps employed are run up to an unreasonable and unsafe speed. In nine out of every ten such cases the machinery will give way under the strain and great expense in repairs and loss of time are sure to follow.

The porphyritic rocks of this district are quite porous, and contain a great deal of water. To drain the accumulated water of this rock it is far more practical to proceed in a steady, sure manner, than with undue haste. The permeability of the rock is not very great and consequently, after the workings have been drained, the flow will continue for some time to an extent that precludes economical working, and nothing is gained by hasty work.

The opinion that much of the water encountered in the deeper shafts about Leadville comes from caves and fissures is entirely erroneous, but that such a belief exists among the miners is proved in the frequently repeated statement that a lake of water has been encountered.

It is true that occasional channels are encountered underground, carrying streams of considerable magnitude, but if followed up they dwindle down and soon prove to the observer that they are fed entirely by drippings from pores in the rock along their course. The interstices and pores of the Leadville porphyry are capable of holding more water than one who has not observed this characteristic of the rock would believe. The permeability of the porphyry varies largely, and where in one section the surrounding country is comparatively drained in a short time, in another it will take two and three times as long.

That the bulk of the water encountered in the Leadville mines is stored in the minute openings and pores of the rock is demonstrated by the past experience of the wet mines of the district. For six months or a year the flow of a wet shaft continues almost unaltered; after that time a gradual decrease is noticeable, until finally the minimum is attained and the flow is regular, being influenced only by capillary action.

Two years ago large pumps in the Wolfstone, Brookland, Clontarf and Big Chief shafts, failed to keep the mines in this portion of the hill sufficiently free of water to permit their steady operation. Months of pumping has, however, liberated the hill of its accumulation of water, and now less than two pumps control the entire flow. And it is safe to say that within two years one pump will be able to do the work which four failed to accomplish in the early days of these mines.

ANOTHER OLD MINE.—Peter Woolcock, of Mill City, recently returned from Denver, Colorado, where he went with a carload of ore from the Sheba mine, in Star district, Nev. The ore assayed over 800 ounces of silver to the ton, and yet the Sheba mine, which produced it, has been lying idle for years, Mr. Woolcock being the only person who would risk what money was necessary to get it in working order.

At Manchester, England, a meeting of the delegates of the various miners' associations throughout Great Britain was held, when a resolution was adopted approving the demand of the miners for an advance of 15 per cent on their present wages, but it was decided to take the halo of the whole of the operatives on the question before ordering a general strike. The delegates represented 109,000 men.

A SEATTLE dispatch says: "The Chinese have all been discharged at the various coal mines in this vicinity. Many of the mills are also displacing the Chinese in their employ by white laborers. The trouble at the Franklin mine, which promised to be a violent outbreak, was avoided by the Chinese taking the alarm and leaving the mines, as requested by the white miners."

LIEUTENANT GOVERNOR DAGGETT, of the Black Bear mine, will shortly commence the construction of an incline railway to convey quartz from the mine to the mill, dispensing with teams and wagons which have been used heretofore. It will require 11 tons of iron for the track, all of which will have to be packed over Salmon mountain on mules.

THE Belmont (Nev.) *Courier* says: Now that the ranchers have harvested their crops, they are troubled to find a market for their produce. As the stagnation in mining continues, they will discover that when the main industry of the State is under a cloud, farming is bound to suffer.

EXPLORERS to Queen Charlotte's Islands, in their report to the British Columbian Government, state that they found resources of timber, arable land, coal and fisheries enough to support a million souls. The islands will probably be colonized.

OVER 400 delegates attended the annual session of railway conductors, at Louisville. The question of establishing permanent headquarters at some suitable place is being discussed.

Manufacturing Sulphur.

Utah, among its many valuable mineral deposits, is destined to become noted for its product of sulphur. As early as 1869 F. Dickert made locations of sulphur claims at Cove Creek, which is now reached by the Utah Central Railway to Black Rock, Beaver county, and by wagon road 26 miles eastward. In all, Mr. Dickert has 23 claims aggregating about 460 acres. After making the locations, he traveled to various countries, and among others, visited the sulphur manufactories of Sicily, from whence comes most of the sulphur used in this country. It took long years of study and experiment to get cheap processes for refining sulphur, and this has been accomplished by Mr. Dickert. He has secured patents on his claims and erected machinery ample for the production of 42 tons per week and in a short time this will be doubled.

The process is simple and cheap. Two large iron tanks are employed. These are made steam tight, and consist of upper and lower sections, the upper being the largest and for the reception of the sulphur rock, a charge amounting to about 21 tons. The lower section is simply a big kettle, having a spout at the bottom to draw off the sulphur in a molten state. A perforated partition separates the upper and lower chambers. After a charge is placed in the upper chamber it is closed tightly, and steam at a pressure of 70 pounds is turned on to heat the mass to a temperature of 111 degrees, when the sulphur becomes melted and finds its way down into the lower chamber. When all is driven out of the rock by heat, a side door is opened and the residue is drawn out and thrown into a waste dump, while the pure sulphur is either run into large cones of brimstone or ground in a mill to make flour sulphur, and then shipped in sacks.

The sulphur rock has been explored in the claims to a depth of 20 feet in numerous places, through rock that runs from 60 to 99 per cent sulphur. We are sure that at no sulphur mines in the world is the rock so pure. Two new tanks, weighing in the aggregate 27,000 pounds, have just been procured to be added to the works, bringing the daily product up to 16 or 18 tons, instead of seven or eight as now. It was only last July that the works began sending out their product, and up to date 25 cars of 14 tons each have gone to market. The question naturally comes up, what is all this sulphur used for? end this question can be easily answered. In 1884 this country imported about 200,000 tons, which found a market for use in the arts, for manufacturing sulphuric acid, etc. In the vast country west of the Missouri river, during the past year, it required over 20,000 tons of sulphur, so estimated, to furnish dip for the vast sheep herds. This is the great remedy known for scab or kindred diseases in sheep, and the demand is increasing. The Cove Creek works employ 18 men and several large teams, the latter to haul the product to the railway. The supply is simply unlimited. Refined sulphur is worth in various markets from \$45 to \$80 per ton.—*Salt Lake Tribune*.

NATURAL GAS IN LOS ANGELES.—The Los Angeles *Mirror* says: "It has been but a few weeks since workmen engaged in boring a well in the western portion of the city, near the new Sisters' Hospital, struck a flow of natural gas. We are not advised as to the quantity of the flow, or whether the well is to be utilized or not, but the fact that such a discovery has been made is very significant. Gas wells are found in defined belts, just as artesian and oil wells are found. Indeed, it is a well-established principle that gas wells are an adjunct of petroleum deposits, the oil being volatilized by the heat in the depths of the earth and confined in caverns and crevices, until given vent by the horer's drill. It is not a great wonder that gas has been found in our western hills, since petroleum has long been known to exist there. As far back as seven or eight years ago Mr. Chandler bored for oil on his place on the Temple street extension, and found it, though not in paying quantities. As a further evidence, there are considerable deposits of breia in the neighborhood, which it is well known is the solidified residuum of petroleum after evaporation. A few miles to the southwest is the Brea ranch, from which thousands of tons of this substance has been derved, and thousands of tons yet remain. But if petroleum and its concomitant, gas, exist under the western hills, it is probable that gas may be found where oil is found, in other portions of the county; notably the petroleum regions of Newhall and the Puente. If gas wells are opened in this county they may be worth more than all the oil yet developed; they may solve the manufacturing problem and add millions of dollars to our taxable wealth."

THE DUNCAN CONCENTRATOR.—Our interior exchanges make frequent mention of the introduction of the Duncan concentrators into various mills in different parts of the country, with most favorable comments as to the satisfactory work they are doing. It is evident that this machine is attracting wide interest and is filling the demand for a cheap and effective method for eliminating and separating the valuable minerals contained in every variety of base ores. The manufacturers report constant orders from many of the most prominent mills of the State, as well as large shipments to Central and South America, and many other distant localities.

Passing Events.

There is considerable interest manifested down about Hawthorne district, Nevada, and a good deal of prospecting is going on. The principal mine of the region has commenced to ship hullion and others will soon follow. It is predicted, too, that Aurora will for the third time revive, and some of her best mines once more be brought into active development. A curious feature in strikes has occurred in this city, where Chinese cigarmakers have quit work because white men were employed in the factory. This is the first instance of the kind on record, and has caused much excitement among the industrial classes in this community.

The rivers continue low. This has been a most favorable season for river mining, on account of the small column of water flowing. The California river-hed miners have been reaping rich harvests this fall.

Mr. C. A. MOREING, the agent for the English syndicate, which has been working the Blue Jacket property for several months, has come into Tuscarora from Blythe City. He informs the *Times-Review* that the entire works are closed down, the men discharged and that the company will forfeit the first payment which was made, and abandon the property.

Who Invented Hydraulic Mining?

The process of hydraulic mining, so long conducted in this State, originated here. When the miners first came to California they used the pan, rocker, tom, sluice, ground sluice, etc., and with the most primitive appliances took out millions of dollars worth of gold. The gulches, hars, flats, low banks and river beds held the concentrated golden sands and nuggets which had been deposited there during the disintegration carried on by Nature. But as these spots became worked out and scarce it was necessary to adopt more rapid systems than those in vogue to obtain the gold. About this period the system of hydraulic mining came into use. Its first conception has generally been credited to E. A. Matterson. Another claimant for the honor was A. Chahot, who is said to have had a hose at work some months before Matterson. Chahot is generally credited with using a hose to bring the water from the top of the bank to the bottom of his diggings, but he used no pipe or nozzle. Matterson is said to have first used his hose and nozzle in April, 1853, at American Hill. We recently heard that Mr. George R. Warren, of this city, was really the first one who devised the plan of turning a stream against a bank through a hose and nozzle. Mr. Warren feels confident that he really was the first to do this, and upon being interviewed told the story to us in the following words:

"There were four of us, John McCargo, Ben Halsey, Samuel McRaider and myself, mining on Selby Hill, Nevada county, near Nevada City in the summer of 1852. We were sinking four shafts, and run a tunnel to tap the shafts to drain the claims, and after we got the drain in we found the claims below were owned by other parties. We then got permission to run our drain tunnel under their ground. Finally we bought their ground and the ravine below with the intention of ground sluicing. This was after the parties below worked out their claims. When we could not get plenty of water we drifted our ground and worked on the surface with a small quantity. When we found that the ground below us, having been worked out, began to come down we had to put in some boxes to drain it for fear it would come down before we got through, but we got our drain in before it did fall. We were huying water from Rock Creek Ditch Company at the time. The claims were small in those days—about 30 feet square. We got water nights and Sundays free, because the company had no reservoirs to save the water. In running the water over the ground we found it loosened the bank. I said to the boys, 'Boys, we can put up something here in the way of water pressure and we can knock this dirt all down out of the way.' They were all in favor of the plan. I went over and got some duck or canvas, twine, needles and a palm, as one of our number understood sail making and could therefore make the canvas part; and we got the tinner, John Kinney, to make the nozzle which was three feet in length, three inches at the butt end, and 1½ inches at the small end.

"I sent the things over by the hutecher, as I wished to keep our plans dark, and said nothing to the tinner as to what I wished the nozzle for. The next morning we commenced to make the flume for carrying the water to the edge of the bank. We then took a sluice and cut it in two crosswise, and took the two parts and fastened them together like a box, to connect with the flume. This box was set on end up from the ground. The water came in at the top end from the flume and we fastened our hose at the bottom end. The lower end of this box stood about three feet above the ground, so as to give us room to attach the hose. We had it done on Saturday at noon. The tinner's bill was five dollars. He wanted to know what I was going to do with the horn or nozzle, and I told him it was to call the boys to dinner. I stopped to see Horton who was running the water office, and told him we wanted to get water from Saturday night to Monday morning, and he let me have it free. We got pine knots so as to have plenty of light to work by at night and started this 'hydraulic.' People below did not know what so much running water meant and about 500 miners visited the work before Monday morning. It just took the bank right down. It was not a week before they had one on Oregon Hill. Some put up sluice boxes and just attached a nail keg; afterwards improvements were made."

"Matterson was working on the other side of the ridge a mile and a half down; he may have seen our rig that Sunday. We laughed at the idea of Matterson getting a patent on that. The dirt we got before running the 'hydraulic' was pretty rich, and it paid a great deal better after the 'hydraulic' was put in. We got about \$2800 from just the top dirt. Afterwards I sold out and went to Dutch Flat in about 1855."

Tunnel Work.

The Big Bend Tunnel, Butte county, in this State, is now in 10,197 feet, and will be 12,000 feet long when completed. It is intended that the river shall be turned through the tunnel when completed, so that about 14 miles of the river bed in the Big Bend may be worked. The tunnel will cost about \$600,000 when complete, though the original estimate was between \$500,000 and \$1,000,000. The ground and tunnel are owned by a Buffalo, N. Y., company, Dr. R. V. Pierce now having four-fifths of the stock. Dr. Pierce, who is President of the company, is now in this city, and in conversation with him this week we gained some facts concerning the operations on the tunnel.

It is expected that the tunnel will be completed in April, and the river will be turned through as soon as it is low enough. The tunnel was commenced three years ago, and has only been driven from one face, but very rapid work has been done. They have been lucky in not meeting much soft rock, which would necessitate timbering.

Last month they made 405 feet progress. A 30-foot grade is the minimum in the tunnel, and where the water is first taken in it is quite steep. The superintendent does not think there will be any use in trying to save gold in the tunnel itself, as the current will be so swift. The river bed that is left dry by the turning of the river itself will be worked by pick, shovel and sluices. There is no very great depth of slickens, as the mining which has been done above has been mainly drift and bar work. They will work the river bed in half a dozen places at once. There are some rapids and falls in the 14 miles of bed, and plenty of places to get rid of the tailings. Some water will be brought from the head dam as far as French creek, and below that this creek will give about 400 inches. The bed of gravel is not very heavy, the current at the Bend being pretty swift. Tests have been made at different parts, where they have used coffer dams to get at the bottom, and rich prospects have been found. All the exposed portions of the bed have been worked thoroughly in years past.

They have lately made a horse trail entirely around the Bend, which has been quite a difficult job, since it is in a deep canyon, the sides in some places being very precipitous. A telephone line will soon be constructed.

Dr. Pierce attributes the rapid work accomplished to the fact that their drilling machinery is very perfect and that they have had good men to manage the work. The rock has been hard and only two places have had to be timbered. Mr. N. A. Harris, formerly superintendent of the Spring Valley mine, and then of the Miocene, is superintendent, and is a very competent man. The company is highly pleased with his services. The tunnel foreman, who was recommended to the company by Parke & Lacy, agents of the Burleigh Drill Co., has also proved himself a good man. He has had considerable experience, having worked in the Hoosac tunnel, and in the tunnels built by the C. P. R. R., on this coast. Dr. Pierce also states that the Burleigh drills and compressors have been very satisfactory in every way. Two compressors are in use, one a Burleigh, and the other a Clayton. The drills are of the largest tunnel size, and there has been very little breakage or delay compared with what other companies have experienced in drilling work.

They have a very perfect system of ventilation in this tunnel, so that the men work as comfortably now as when in only a couple of thousand feet. The powder fumes and bad air are exhausted by a large Baker blower acting as an exhaust. Fresh air is, of course, sent in by the compressors to the drills at the face. Therefore a good current of air is kept flowing in and out, and the temperature at the face of the tunnel is kept at about 62 degrees.

The Drum Lummon mine uses compressed air entirely for hoisting and drilling.

Mining and the University.

At the last meeting of the Board of Regents of the University of California, a Professor of Mining and Metallurgy was appointed—Mr. S. B. Christy who has been instructor in those branches being selected for the position. Wm. Ashburner has been for some years, and still is, Honorary Professor of mining, but has taken no active part, owing to his other business requiring all his attention.

The new Professor of Mining and Metallurgy, S. B. Christy, graduated from the college of chemistry at the University of California in 1874, having taken in addition all the principal studies of the engineering course. After graduation he pursued these studies of mining under the direction of Prof. Ashburner, metallurgy under Dr. Becker, and mechanics under Prof. Hesse. In 1879 he was appointed Instructor of Mining and Metallurgy, Dr. Becker having resigned to take charge of the Nevada Division of the United States Geological Survey.

During the last few years Professor Christy has had charge of the work in mining metallurgy and assaying, having also designed and superintended the entire equipment of the assaying and metallurgical laboratories of the University. In order to make himself familiar with the actual needs of the coast he has visited and studied the best examples of silver mining and milling, gold mining, amalgamation and chlorination, silver lead melting, hydraulic and drift mining, and the reduction of quicksilver ores. The courses of instruction in all the technical branches are framed to meet the actual needs of these important mining industries of the Pacific Coast.

Professor Christy was for some time associate editor of the *MINING AND SCIENTIFIC PRESS*, translating for it the "The Mines and Works of Almaden" (afterwards published separately by Dewey & Co.), and contributed many articles on other subjects, such as "Oakland Harbor Improvements," "Low Water Gas," "South Pacific Coast R. R.," etc.

Prof. Christy has been for some years Corresponding Secretary of the California Academy of Science, and has read before that body papers on "Ocean Placers of California," "Mount Diablo Coals," "Genesis of Cinnabar Deposits," "The Mines and Works of Idria, Austria" (published by J. B. Randol). He has also read the following paper before the American Institute of Mining Engineers, which were published in their transactions: "Miners' Fund of New Almaden," "Quicksilver Reduction at New Almaden," and "Quicksilver Condensation at New Almaden." Prof. Christy is a student who keeps abreast of the times with the improvements in his special branches, and brings to his new position energy and experience which will be of benefit to those in his charge.

The Mining College at Berkeley now offers excellent facilities for students. Besides the assaying laboratories, now excellently equipped, and the new metallurgical laboratory, now in process of equipment, its students have the advantage of the mechanical laboratories and machine shops, under Professor Hesse, the physical laboratory, under Mr. Slate, the chemical laboratories, under Professor Rising, the fine collection of surveying instruments, under Professor Soule, and the well-arranged collection in mineralogy, petrography and economic geology, under Mr. Jackson. The mining course is necessarily one of the most difficult at the University, but has always been a popular one. Some of its students have come from Mexico and South America, and some from the Eastern States. The graduates are already taking responsible positions in the practice of these professions. The assaying laboratories are fitted for all sorts of work in that branch. A building has been constructed for the metallurgical laboratory for experimental purposes. They have a 15-horse-power Westinghouse engine, a 15-horse-power Babcock & Wilcox boiler, and orders are out for other machinery. As soon as the appropriation of \$10,000 becomes available this department will be completed.

AUSTRALIAN COPPER.—United States Consul Griffin, at Sydney, has sent to the State Department a long report on the Australian copper mines. He says that the copper mines of Australia are among the most famous in the world. They are so rich that they produce a metal in many respects quite equal to the best Lake copper of the United States.

Cheap Milling.

In speaking of the operations at the Alaska mine, Sierra county, in last week's *Press*, the cost of mining was given at \$5.70 per ton, and of milling at \$6.64. This \$6.64 really represented the combined cost of mining and milling, as the cost of treatment at the mill is really only a little over 93 cents, or, to be accurate, 93.5 cents. The milling has been done with 20 stamps, kept in almost constant use, crushing on an average nearly 50 tons every 24 hours. One valuable feature of the ore from the mine is its free milling qualities. The higher grade ore is remarkably free from sulphurets, and when they do occur in greatest quantity they are of so low grades as not to meet the cost of shipment and treatment. Thorough tests in this particular were made during the year, and the fact abundantly proved that unless great changes occur with greater depth in the mine, it will be unprofitable to purchase concentrating machinery for saving them.

The milling at the Sierra mine is conducted on a plan as adopted by Mr. J. M. Davis, the experienced amalgamator and millman, using mortars with high discharge, amalgamating as much as possible in the battery. Over 80 per cent of the gold saved never leaves the mortars. The only other appliances used are the ordinary silver-plated aprons and sluice plates, extending from the battery and a series of riffle boxes extending from the mill, to gather any amalgam that may escape the plates. The mine now being able to furnish 100 tons of ore a day, and the engine and boiler being of capacity to run 40 stamps, 20 more stamps are being added.

Mill supplies last year cost \$2372.10, which included shoes and dies, cams and tappets, quicksilver, screens, chemicals, etc. The mine produced in the 11 months between Oct. 1, 1884, and Sept. 1, 1885, in bullion, \$175,456.07. The milling account in detail is as follows:

Fuel (wood).....	\$ 3,575.00
Labor.....	6,875.00
Wear shoes and dies (including freight).....	1,561.00
Loss in quicksilver and chemicals.....	80.00
Oil (light and lubricating).....	165.00
Screws.....	129.75
Repairs (including boiler).....	700.00
Total.....	\$13,085.75
Ore milled.....	14,000 tons
Cost of treatment per ton.....	93.5
Ore extracted.....	14,300 tons
Cost of mining per ton.....	\$5.709
Cost of mining and milling per ton.....	\$6.644

New Design for Small Steamers.

A steamer has just been completed by Capt. Matthew Turner of this city (whose shipyard is at Benicia, Carquinez straits), which is of a rather peculiar form. She is intended as a dispatch boat for use on the Gulf of California, where she will carry passengers and water. The vessel is 82 feet long over all, 18 feet beam and 13 feet depth of hold.

The peculiarity in the design consists in the reversed shear given the hull. The shear is 2½ feet reversed from a straight line. Vessels built on the ordinary form have more or less shear. The shear of a vessel is the longitudinal curve of her deck or sides, causing it to look lower in the middle than at the ends. This new steamer has the shear reversed. That is, she is higher in the middle than at the ends. The ordinary shear would be in one of her size 2½ feet, but with the 2½ feet added above the straight line, it gives her five feet more height amidships than if she were built in the common way.

The object of this peculiar construction is to give more room and height below deck, and do away with the necessity of building cabins, etc., on deck. In so narrow a boat the deck-houses would have to be narrow to have a passage around them, which would give cramped accommodations. As built, the deck is perfectly free, nothing but a low pilot-house projecting above. This pilot-house is a "hanging one," the floor being three and one-half feet below the deck, and roof three and a half feet above. The reversing of the shear of the vessel gives room for 24 tons more coal than could be carried had she had the usual form of shear. The "free-board," or height of deck-line above water-line is eight feet. The appearance of the steamer is rather novel, but the new form is one which admits of strength of construction, and gives much more room below and on deck. It makes a "big little boat," looking something like a turtle-back torpedo boat.

A speed of ten miles an hour is guaranteed under steam, but masts and sails are provided

also. The whole deck can be utilized, and awnings spread during the hot weather that prevails where the steamer is to be used. In the bottom of the steamer, forward and aft, are fitted tanks which carry 3874 gallons of water. The vessel carries water to islands in the gulf where there is no natural water supply.

The cabin floor is dropped two feet below the line where it would naturally come in an ordinary vessel, giving five feet eleven inches head-room aft and six feet forward. There are four state-rooms. The cabin is 15 feet wide and 20½ feet long. The peculiar form of the vessel gives a truss shape above, so that she is unusually strong. It would seem that this style of construction would be useful in many small steamers. Being high-sided, she will be dry in a sea-way, and the whole deck is free for use, being inclosed by a high open rail. The steamer is called the *J. Romero Rubio*, and was built on the order of Captain Bruce, of this city.

The Rowell Safety Stove.

We examined this week, at the office of Dr. Charles Rowell, 426 Kearney street, in this city, a peculiar safety stove for railway trains which he has patented. As an improvement in heating apparatus for such purpose, and an im-

provement in the direction of providing safe and economical stoves for special uses of this character, it is claimed for this invention that the two features of absolute freedom from danger of overturning and breaking in time of accident, and a large heating power in proportion to fuel consumed, are secured in a most complete manner, and without adding to the general expense of manufacture, or creating difficulties in the management of the stove when in use.

The accompanying engravings give a good idea of the appearance of the stove with some of its details of construction. Stout wrought-iron bands encircle the stove, and suitably connected with them is a peculiarly constructed skeleton frame constituting a perfect fender to prevent contact of the heated stove surfaces with surrounding objects and surfaces, and with the bodies of persons when thrown against the stove, as well as an absolute guard against rupture or breaking in of the body by crushing forces under the most extreme conditions of pressure to which it may be subjected. Casualties arising from the escape of burning coals, and the terrible experiences of death by burning that are not uncommonly associated with railroad disasters in all countries at the present day, may be prevented by the application of this improved armor on the Rowell stove. This frame or armor consists of strong rings encircling the stove and upright rods connected to them so as to form really an independent structure which encloses the stove proper. These upright rods four in number, cross under the stove so that through them it is bolted immov-

ably to the floor. The method of securing to the floor is shown in Fig. 2. This gives security against overturning, while at the same time the fastenings are of such a character that by removing the washer and nut the stove may be removed and reset as occasion may require.

In regard to the burning and heat producing qualities of the Rowell stove, these are secured and increased over stoves of like character, by the application and peculiar construction of a combustion chamber in the upper part of the stove body above the fuel space, in which the smoke and other partially decomposed and imperfectly consumed particles and the gases and vapors from the fuel are subject to further and more complete combustion, so that instead of being carried off by the draft, this matter is converted into heat by undergoing final reduction within this space through which it is compelled to pass. This chamber is formed at the upper portion of the stove directly over the fuel space, by means of a peculiar arrangement of perforated diaphragms placed between the fuel space and the smoke outlet, and by the use of adjustable dampers, the communication of this chamber with the smoke and draft passages, and its connection with the fuel space or chamber, are regulated in such manner as to secure the most effective action and results.

In this feature the construction is designed to

Fig. 2—Fastenings of Stove to Car Floor.

Fig. 1.—Fastenings to Doors and Covers.

THE ROWELL SAFETY STOVE.

give complete control of the gases, and imperfectly consumed matter from the fuel, and at the same time to secure full and efficient draft. All the openings in the body for the supply of fuel, for draft and for cleaning purposes are protected by guards that confine the fuel and flames without interfering with the special functions of the openings, and special locking devices to the guards or covers of the openings form fastenings that are readily operated but will not release the covers or doors unless so moved by hand. This latter feature is quite ingenious and is shown in Fig. 3. By means of the lugs on the locking-bar and a series of irregularly set grooves on the hinges or pintles, the locking-bar must be turned back and forth four times before it can be withdrawn to open the doors. No accidental overturn could accomplish the peculiar movements being required.

These improvements have been perfected without effecting the symmetrical appearance of the stove or materially increasing its size. The frame is strong enough to bear a weight of eight or ten tons on any part. The fender rings are secured to the circular flanges by V-shaped wrought-iron lugs in a very strong manner, and the whole skeleton frame acts as a radiator. The rods run across the top and bottom as well as at the sides. The arrangements for regulating the draft without leaving exposed openings are ingenious and practical. Dr. Rowell states that he is able to utilize all the heat from the fuel and allow no waste. The invention presents no difficulties in the way of manufacture. The stove appears to be a very perfect contrivance for the use for which it is intended, and

give complete control of the gases, and imperfectly consumed matter from the fuel, and at the same time to secure full and efficient draft.

All the openings in the body for the supply of fuel, for draft and for cleaning purposes are protected by guards that confine the fuel and flames without interfering with the special functions of the openings, and special locking devices to the guards or covers of the openings form fastenings that are readily operated but will not release the covers or doors unless so moved by hand. This latter feature is quite ingenious and is shown in Fig. 3. These improvements have been perfected without effecting the symmetrical appearance of the stove or materially increasing its size. The frame is strong enough to bear a weight of eight or ten tons on any part. The fender rings are secured to the circular flanges by V-shaped wrought-iron lugs in a very strong manner, and the whole skeleton frame acts as a radiator. The rods run across the top and bottom as well as at the sides. The arrangements for regulating the draft without leaving exposed openings are ingenious and practical. Dr. Rowell states that he is able to utilize all the heat from the fuel and allow no waste. The invention presents no difficulties in the way of manufacture. The stove appears to be a very perfect contrivance for the use for which it is intended, and

the general design of the structure may be said to have considerable merit from an artistic point of view. Various sizes may be made; the one we examined being the largest size railroad car stove. The invention is one that entirely obviates the chances of fire when railroad accidents occur, without changing in any degree the ordinary heating appliances.

Copper.

Liverpool and Swansea have imported during the first nine months of this year 22,246 tons of copper from Chili, and 18,742 tons from the United States. In 1882 those two cities imported 20,150 tons from Chili and 521 tons from the United States. These comparative figures will show how we have increased our copper product. From sending 521 tons of copper to Liverpool and Swansea in the first nine months of 1882 we increased to 6000 tons in 1883, and 12,752 tons in 1884, and 18,742 tons in a corresponding period this year. The imports from other countries than Chili into Liverpool and Swansea for the first nine months of the year aggregated 37,890 tons, including that from this country.

James Lewis & Sons' reports give the stocks of Chili produces on hand now as 28,948 tons fine, and the total visible supply of copper as 56,625 tons. Latest English quotations are £40 10s. for Chili bars. Ore of 25 per cent, 7s. 6d. to 7s. 9d., and regulus or matte, 7s. 9d. to 8s. per unit.

Statistics show that the excessive import of copper into England and France during the past nine months has been almost entirely from America and Japan. The import from Chili has been 3973 tons less than last year, that from Spain 502 tons less, and from other countries 686 tons more. From the United States the increase has been 10,130 tons, and from Japan into London 2450 tons, the import of Australian there showing an increase of 150 tons, but a decrease of 273 tons into Liverpool and Swansea.

Lewis & Sons' Liverpool report says: The market has been adversely affected by the decline in silver to 47½d. per ounce, and the consequent withdrawal of orders for India, and by the large arrivals here and to France, causing an increase in the stock of 1755 tons, and by the negotiations pending for the renewal of a contract for a large quantity of American matte. Early in the month, sympathizing with the advance in iron, Chili bars improved 10s. per ton, but have since steadily declined from £42 17s. 6d. for cash on the 8th ultimo, to £40 2s. 6d. on the 25th. This low figure induced considerable buying, but we close with sellers of cash bars at £40 10s., and of three months, at £41 2s. 6d. per ton; 4000 to 5000 tons (2000 pounds) of Lake Superior ingots have been sold to American manufacturers, for delivery during the remaining months of this year, at 11 cents per pound, equal to £53 12s. 6d. per English ton, less two and a half per cent. discount, or about £7 above the present value of English best selected here.

QUICK BRIDGE BUILDING.—A week ago last Saturday the railroad bridge over the Colorado river burned down, as we stated in the *Press* at the time. Since then a temporary bridge has been built, and mails and passengers are enabled to come through on time. The erecting of the temporary structure is one of the quickest pieces of work on record, and was done under the supervision of Arthur Brown, superintendent of bridges for the company. When it was known that the bridge was burning, timbers that are kept in readiness in Oakland and at the yards in Sacramento were run out. A large number of bridge builders and carpenters were summoned, and before the smoke of the charred timbers had floated away the men were at work on a temporary bridge with the above result. The old bridge will be rebuilt at once.

MINERALS ON SCHOOL LANDS IN TERRITORIES. In reply to an inquiry of the Commissioner of the Land Office respecting the Interior Department order instructing him to "suspend all action relative to mineral applications for school lands in the Territories until further notice," the acting Secretary of the Interior advises the Commissioner that the same was not intended to refer to claims initiated upon unsurveyed lands which may possibly by subsequent survey be found to lie in a school section, but was directed to a possible question as to whether or not mineral lands, as such, are exempt from the reservation of 16th and 36th sections for the support of schools.

MECHANICAL PROGRESS.

THE MECHANIC OF TO-DAY.—Lahor, to day, is not what it was two generations ago! modern improvements have made workmen more of a machine than an intelligent artisan. Instead of a long apprenticeship and the mastery of a whole "trade" one gets, in a short time, a proficiency in one thing, and that is all he learns to do. The truly skilled mechanic is becoming a rare bird. The fault is not alone in the present style of manufacturing; the workman himself is partially to blame. It is impossible to secure apprentices. The boy who wishes to learn a trade refuses the best chances offered when not accompanied by wages far exceeding any possible value he can be to his employer. If, perchance, he engages to work, excesses in tobacco, liquor and similar vices so unnerve him that hard work "hurts him," and his health is affected. He is indolent, his leisure hours are occupied in any way but beneficially, and every parade and excitement must find him a spectator. The offer of a few cents more per week causes his abandonment of his place without notice to his employer, and he grows up full of expensive habits, unfit to support or care for himself, to say nothing of marrying or rearing a family. The war made many tramps, but the degeneracy of our boys is making more.

CORROSION.—The *Locomotive* says that "leakage at the tube ends is one of the most frequent and annoying defects to which the ordinary horizontal and upright tubular boilers are subject." It adds that the corrosion which this leakage induces speedily brings about a dangerous condition of affairs. This statement of the case is undoubtedly correct, but when our contemporary argues for the pound of cure we must part company, because our preference is decidedly for the ounce of prevention. The one thing better than to be continually tinkering with boiler head and tubes is to manufacture the boiler of a material that is the least liable to corrode. Such a material is refined iron, and its use insures the greatest possible immunity from corrosion and its attendant annoyance and dangers. The manufacturers of steel plates have of late been using a magnesia "physic" in their crucibles, and thereby greatly increased the tendency of their product to rust out. But they do not dare leave the magnesia out, for then the gas cells in the ingot will be found as great flaws in the plates that come from the rolls. To grasp either horn of the dilemma seems fatal. Without magnesia steel plates are full of flaws; with magnesia the plates corrode. Refined iron is free from either fault.

TESTING LUBRICANTS.—It is a matter no doubt often overlooked in testing lubricants that experiments made upon the nicely fitted journal of a testing machine are not conclusive as to the fitness of a lubricant for use on a similar journal which is not well fitted. As the latter hears only in spots or along lines of contact, it is subjected on such surfaces of contact to pressures which may be enormously heavier than that affecting the same journal when wear or refitting has given it a good bearing. Could its magnitude be known, a good testing machine would determine which of any collection of oils is the best fitted for use upon it. The testing machine determines the behavior of an oil upon its own journals, and only if those on which the lubricants is to be used are similar will its behavior be the same. While the machine does not usually serve to select oils for badly made lubricated surfaces, it exhibits the intrinsic qualities of the oils tested, and every mechanic and engineer endeavors to get all journals into as good condition as those of the testing machine, and thus fit them to do good work with good oils.

AMERICAN MECHANICS COMPLIMENTED.—In his late address before the Mechanical Section of the British Association, Mr. C. E. Baker said: "The magnificent steel wire rope suspension bridge of 1600 feet span, built by Roebling across the East river at New York, well marks the advanced state of mechanical science in America, as regards building. It is worthy of note that, at the second meeting of the British Association, held in 1832, there was a discussion on suspension bridges, and the author called the attention of the scientific world, and particularly of civil engineers, to the serious consideration of the question: How far ought iron to be hereafter used for suspension bridges, since a steel bridge of equal strength and superior durability could be built at much less cost? 'I earnestly call upon the iron masters of the United Kingdom,' said he, 'to lose no time in endeavoring to solve this question.' In this, as in many other engineering matters, Americans have given us a lead. America is indeed the paradise of mechanics."

WATER GAS STEEL.—Bull's patent process of steel manufacture by means of water gas—converting ore into steel without first making pig—is thus described: The gas producers are similar to the Strong and Lowe, or the quasi recuperative type. The coal is forced by a hot blast of air into partial combustion, the resultant heat of which is collected into separate recuperators. An interval follows, during which the air is turned off, steam is forced in a reverse direction through the recuperators, and becoming highly superheated, is decomposed or transformed into a powerful reducing gas. This is led through conduits to the tuyeres of the

blast furnace. It is expected from the careful arrangement of the crucible of the blast furnace, which is of the cupola form, that a bath of pure iron can be maintained in a fluid condition. When the metal is tapped it will be carried by ladle, and run into a Siemens open hearth steel furnace.

NEW PROCESS FOR PRODUCING STEEL.—The *Boston Journal of Commerce* says: A new process of producing steel has been invented by Harry Oliver and J. P. Witherson, of Pittsburgh, by which steel is manufactured about \$5 a ton less than puddled iron can be put in the form of muck bar. At a recent meeting of the Board of Mining Engineers in New York city, a paper was read on the new process by Captain Robert W. Hunt, of Troy. The paper demonstrated that from actual experiments pig iron containing from five to six-tenths of phosphorus produced steel that did not break until it showed 74,000 tension strain, with 25 per cent of elongation. Experiments have been made which seem to show conclusively that instead of phosphorus being a dangerous and weakening element in iron or steel it could be made an element of much value in their manufacture. The new process of utilizing phosphorus does away with puddling and produces fine steel ingots at the blast furnace at a cost of not more than \$4 above the cost of the production of ordinary pig iron. Should the new process prove to be all that is claimed for it there will be a great revolution in the iron industry in the near future.

MAKING RAZOR BLADES.—Razor blades are forged from cast steel, and are ground and scorched to take off the black scale, being heated in a coke or charcoal fire and dipped obliquely into water. After being drilled and stamped they are hardened and tempered. In tempering they are laid on their backs on a clear fire and are removed as their edges attain a pale straw color. Shavings of leather added to the fire prevent cracking when the blades are put into water. After tempering they are ground successively on stone, a lap charged with fine emery and a second lap with finer emery. The final polish is given on a soft leather wheel charged with crocus, both razor and wheel being heated. It is then honed, working from the point to the heel, being laid flat for the purpose. Wire edges are rubbed off on a horn.

FOR WELDING IRON, as is well known, the pieces are heated to whiteness. When iron is to be welded to iron this plan answers well, but if iron is to be welded to steel the white heat often destroys the steel. To prevent this—according to a newly-invented process—the surface of the metal to be welded is moistened with water, and on the wet surface there is sprinkled a compound of one pound each of pulverized calcedonite, horax and iron filings, and four ounces pulverized prussiate of potash, intimately mixed. The two surfaces are then wired and raised to a red heat, or about 600 or 700 degrees Fahr. When subsequently subjected to rolling or hammering, the joint is completed, while the steel is not sufficiently raised in temperature to be at all injured by the operation.

MEASURING FOR BELTS.—A prominent firm gives these directions: When convenient, measure the distance round the pulley with a piece of marine or tarred rope (it will not stretch as a tape line or string will), and cut your belts, if to be butted, about $\frac{1}{2}$ inch short for every 10 feet in length of marine; if endless, allow for lap. When not convenient to measure the length round the pulleys, add the diameter of the two pulleys together, divide the result by two, and multiply the quotient by three and one-quarter; add the product of twice the distances between the centers of the shafts and you have the length required.

HOT BLAST AND COLD-BLAST PIG-IRON.—They are named from the temperature of the blast used in smelting the iron. Hot-blast generally is more economical, but the metal is not considered to be so strong. Difficult to distinguish the two varieties, but, other circumstances being equal, hot-blast iron has rather a finer grain, duller fracture, with sometimes patches of coarse grains, and usually more impurities. Increasing the blast or reducing the supply of fuel makes the iron whiter, harder, and less suitable for remelting, but better for conversion into wrought-iron or steel.

A NEW FILE CUTTING MACHINE.—There is being built at the Chicago Die and Machine Works, Chicago, a new file-cutting machine, the patent for which has just been issued to H. F. W. Liehmann, of Chicago. In this machine the file-blank rests on a platform or table, the chisel is brought down to the file and given a blow by the hammer, and this process is repeated automatically, the chisel and hammer being raised sufficiently. The movement is by hand.

SPRING POWER FOR SEWING MACHINES.—By using a cone spring, sewing machines are now driven without the aid of foot or hand power. A few turns of a handle winds up sufficient power to keep a machine going at full speed over half an hour. It is completely under control as to the rate of stitching and stopping, and can be applied to any existing machine at moderate cost.

SCIENTIFIC PROGRESS.

Colors Large and Small.

It has long been known that size is an attribute of color, at least so far as the object is presented to the eyes. A white object appears larger than a black, etc., but it has recently been stated that Prof. Huxley has discovered that there is something more than mere appearance in this phenomenon—that colors are really large or small. It is stated that Prof. Huxley's attention was called to the matter quite accidentally through the medium of stockings. He had bought six pairs of stockings of the size known as No. 10. Three of them were red and three blue. On trying them on he found that the blue stockings were too small and the red rather too large. As they were all No. 10 stockings, it was evident that the difference in size between the red and the blue pairs was due to their respective color. Pursuing his investigations in connection with stockings, Prof. Huxley found that white stockings are larger than either red or yellow; that black stockings are smaller than blue ones, and that, in short, there is a regular scale of size in colors reaching far back up to white. The reader will probably receive this announcement with some degree of credulity; but, at all events, it is quite evident that color has much to do with the size of objects as they appear to the eye, whether the measuring sale will confirm such impressions or not.

White is the largest of colors. White letters on a black ground can be seen much further than black letters on a white ground. A woman in a white dress is larger than she would be in blue, and very much larger than she would be in black. Women long ago intuitively grasped the fact that black is the proper wear for a fat woman. Dressmakers have been accustomed to say that a black silk dress makes a stout woman appear reasonably small, but we know now that it actually and literally reduces her apparent size. Nearly everyone has met in summer time a fat German dressed entirely in white, but a thin white-clad German is something entirely unknown. Of course, it is the white dress which makes the German fat. Dress the same man in black clothes and he would be a man of ordinary size. The world has long known that the red-coated British soldier is a larger and braver man than the blue-coated Frenchman, but it has never hitherto occurred to any one that the difference in size is due to the difference in color. Time and space would fail to allude, even in the most cursory manner, the various ways in which colors may thus deceive the eye.

THE RECESSION OF THE FALLS OF NIAGARA.—Sir Charles Lyell, in 1841 and 1842, estimated the gradual recession of Niagara Falls by the undermining of its brink at the rate of about one foot per annum. Recent investigations of the subject by a commission for the establishment of a State reservation at this Falls have, however, shown that this and other estimates are more or less erroneous. A map, based on surveys of the Falls made in 1883 by Mr. Thomas Evershed for the New York State Surveyor, has shown that in the 41 years ending 1883 the annual rate of maximum recession has been 6.16 feet. For the eight years ending 1883 this rate is given as 16.5 feet, so that the rate of recession has been higher of late. These results were obtained from the Canadian Fall, while the American Fall was found to have receded at the rate of 10 inches per annum during the 41 years ending 1883. It has been shown by the surveys that these two falls were once united; and that, supposing the rate of recession to continue, the Niagara gorge will be cut through in some 10,000 years. Lyell's estimate was 35,000 years. Of course these attempts to calculate the cutting of the entire gorge, which terminates at the heights near Lake Ontario, assume that the hardness of the shale and lime rocks, volume of water, and height of the fall, continue much the same as they are now.

QUARTZ DEPOSITS.—The crystalline form of quartz grains in some sandstones has been seen by many observers, while especial attention was called to these forms in the Wisconsin sandstones by Rev. John Murrish in 1870 and later. Mr. H. C. Sorby, in 1880, showed that such crystal forms were produced by the deposition of secondary quartz upon the irregular rounded surfaces of worn quartz grains. For the Wisconsin sandstones, the subject was taken up by Rev. A. Young, and later by Messrs. R. D. Irving and C. R. Van Hise, who have published an extended and valuable paper (*Bull. U. S. geol. surv.*, No. 8), with full illustrations, relating to the enlargement both of quartz and feldspar grains; and for this the thanks of all micro-mineralogists and lithologists are due. Our authors conclude that their results prove that most, if not all, of the ancient quartzites, as well as many of the quartziferous schists, are composed in the main of fragments cemented together by a secondary siliceous cement.

SCIENCE ACCEPTS NOTHING BUT THAT WHICH IS TRUE.—In science nothing can be permanently accepted, but that which is true, says *Popular Science Monthly*, and whatever is accepted as true is challenged again and again. It is an axiom in science that no truth can be so sacred that it may not be questioned. When

that which has been accepted as true has the least doubt thrown upon it, scientific men at once re-examine the subject. No opinion is sacred. "It ought to be," is never heard in scientific circles. "It seems to be," and "we think it is," is the modest language of scientific literature. In science all apparently conflicting facts are marshalled, all doubts are weighed, all sources of error are examined, and the most refined determination is given with the "probable error." A guard is set upon the bias of enthusiasm, the bias of previous statement, and the bias of hoped-for discovery, that they may not lead astray. So, when scientific research is a training in observation and reasoning, it is also a training in integrity.

THE NUMBER HABIT.—In a carefully written paper read by Dr. C. S. Minot before the late American Association at Ann Arbor, the author referred to numerous experiments made under the auspices of the American Society for Physical Research, to determine, if possible, whether the so-called mind-reading had any basis in fact. In the course of these experiments, numbers were used, one person thinking of a number and another trying to guess what it was. On the doctrine of chances, the percentage of numbers rightly guessed should have been 10; but actually it was 18. The difference was explained by the author, by the fact that many persons formed what he called a number habit; i. e., they were much more likely to think of some number than of others; and two persons having the same habit would guess more frequently the numbers usually thought of than chance alone would account for. So far as the experiments of the American Society went, they did not supply any reason for a belief in mind reading; but the English Society had obtained results that seemed to show that it was possible, so that judgment should, for the present, be reserved.

ZINC IN PLANTS.—The presence of zinc in plants has been repeatedly observed, and not only in such as grow near deposits of zinc ores, but also, though in minute quantities, in plants where no zinc could be traced in the soil. From a number of experiments the author found that the injurious action of zinc sulphate in solution was more considerable than it had been assumed. In solutions of 1 mg. zinc per liter all plants vegetated undisturbed, while with 5 mg. per liter all perished. Old plants of any kind died more rapidly than young plants. Insoluble compounds of zinc in the soil—such as zinc oxide, sulphide and carbonate—have no perceptible action. The poisonous action of zinc on plants seems to depend on the destruction of the chlorophyll. —Anton Baumann.

THE DISCOVERY OF ANILINE COLORS.—Aniline colors were discovered in 1857 by a chemist experimenting with coal tar refuse, at that time looked upon as a nuisance. He took coal tar naphtha, and boiling it in a retort, obtained a chemical action, which resulted in benzols and nitro-benzole. Adding water to this, the nitro-benzole was deposited in the form of a thick, oily mass. This he experimented with in various ways, and finally by the addition of acetic acid and iron filings, produced a colorless fluid which is aniline. This liquid he treated with different chemical salts, and the result was green crystals of a metallic luster. These he found were capable of producing, under different chemical reactions, the most brilliant and gorgeous hues—the aniline colors of to-day.

SUPPOSED MAP OF THE LOST ATLANTIS.—It is stated that Mr. Meyer, a noted archeologist, has recently made a very interesting discovery on the island of Ziperata. Writing from Nicaragua, he says: "About 42 feet under the surface of an ancient cemetery I discovered a rock, which, judging from the figures it contains, has served in remote times for astronomical observations. On this rock I have found two stone tablets, one of which contains a representation of the world, part of Africa and Asia, united Europe, and this continent. A large continent is situated in the Atlantic ocean, which I consider the mythical lost Atlantis mentioned by some of the ancient authors. The other tablet contains inscriptions of which part is undoubtedly Phœnician."

EARTHQUAKES.—M. Perry, a French astronomer, attributes earthquake disturbances, to the same cause which produces tides—the attraction of the sun and moon. He argues that it is only natural that the great molten mass in the interior of the earth should obey the same laws as the ocean on its surface. He has investigated 5400 different shocks of earthquakes, and finds that such occurrences are much more frequent during the periods of full and new moon, than at other times, and that such shocks are always most violent when the moon was in the meridian at the time of the occurrence.

SOLID CARBONIC ACID.—The manufacture of solid carbonic acid has been carried on for some time by a company at Berlin, Germany. Bottles of steel containing eight kilos of liquid carbonic acid are sold. From these, by allowing the liquid to escape into a cloud-vessel, a quantity of solid acid is obtained which, by pressure into a wooden tube with a wooden piston, can be kept in the form of a small cylinder for a considerable time. A cylinder of about 1½ inches in diameter and two inches long, will take five hours to melt away into gas. The more it is compressed the longer it will last as solid.

ENGINEERING NOTES.

The Ship Railway.

Mr. E. L. Corthell, at the recent session of the American Association for the Advancement of Science delivered an address on the proposed Tehuantepec ship railway, in which he says the time has passed when it is necessary to prove to practical men the feasibility of the ship railway method, therefore he devotes the greater part of his address to the superiority of the ship railway over the ship canal, both in construction and operation. The strategic advantages of the ship railway are very important. Mexico and the United States together can protect the railway against any foreign powers. Our navy can hold the approaches to the Gulf, or in case of a superior force appearing upon one side, that fleet might be speedily supported by ships from the opposite side. There is a capacious and protected harbor in the Coatzacoalcas on the Gulf and one in Lake Superior, on the Pacific, and the railroads leading into Mexico from the United States could quickly concentrate a large army at the Isthmus. Seven million tons of freight are in sight for transportation over the railway in 1889. The railway can be built and equipped in four years' time. Fifty million dollars in cash will complete everything ready for business. The estimate in stock and bonds, allowing for all possible contingencies, is \$75,000,000. Even with only 4,000,000 tons, the net profit would be 14 1/2 per cent. The beneficial results cannot be overestimated. Industry, commerce, society and religion, in fact, in all his relations will man be benefited. The success of the projector of the ship railway in his important works—iron-clads during the war, the magnificent bridge at St. Louis, the Mississippi jetties, and other works, gives standing to this new work, and leads to confidence in the ability of Mr. Eads to carry it through to a successful conclusion.

LARGER ENGINES, faster time and longer runs are the order in England as well as in this country. The Northeastern Railway Company is having 20 new engines built solely for express service, which, in several respects, will be unequalled in the world. These are some of the characteristics: drivers—four wheels coupled—7 feet 2 inches in diameter; leading wheels, 4 feet 6 inches in diameter; wheel base, 16 feet 8 inches; cylinders, 18x24 inches; capacity of tender, 2800 gallons of water and 3 tons of coal; weight of engine with steam up, 42 tons, weight of tender, 28 tons, total, 70 tons. These engines will each be capable of running express from York to Edinburgh in one journey, thus doubling the length of run, two now being required. As for their speed, it is stated that on a trial trip one already built made the extraordinary time of 80 miles per hour. However, if American drivers 5 feet 8 inches in diameter can make 72 1/2 miles per hour for 36 miles, as was recently done on the West Shore road, we can believe that wheels 18 inches larger can run still faster.—*Railway Age*.

BUILDING STONE.—Quite an interesting experiment was lately made by the Board of Capitol Commissioners at Atlanta, Ga., to test the relative ability of marble, granite and limestone to resist the effects of heat. Pieces of oolitic Indiana limestone, granite and Georgia marble were placed in a furnace and allowed to remain there for an hour, subject to a white heat. They were then taken out and suddenly cooled with water. The limestone was found to be harder than ever, but the granite and marble crumbled like dirt between the fingers.

TIDE MILLS.—A correspondent at Norwalk, Conn., writes that there are four tide mills within 15 miles of there, and that in dry times this unfauling source of power is greatly appreciated by the farmers, long lines of wagons being seen waiting to have the grist ground. Two of these mills are said to have single-acting turbine wheels, with a simple flap gate to admit water to the pond. Our correspondent suggests that there are, probably, many more tide mills in use in the country than is generally supposed.

A BALLOON RAILROAD is to be constructed in the Austrian Tyrol. The balloon will have grooved wheels on its car, and these will run on nearly perpendicular rails, the gas providing the lifting power. Gravitation will be utilized on the down trips.

PETROLEUM residue is now hurned in locomotives on all the Russian railroads. This form of fuel is likely to be largely used in the future in the place of coal, not only for locomotives, but for steamships.

INDIA RUBBER DEFENSE.—One of the large English war vessels, the Resistance, is to be coated with India rubber to a considerable thickness, to see how that material will repel projectiles.

COKE as a locomotive fuel is now being tested on two locomotives of the New York, Lake Erie & Western railroad that take express passenger trains over the Eastern division of that road.

USEFUL INFORMATION.

HOW TO MANIPULATE GLASS.—Take a twelve-inch mill-file, single cut, and wet it with turpentine saturated with camphor, and the work can be shaped as easily and almost as fast, as if the material were brass. To turn glass in a lathe, put a file in the toolstock, and wet with turpentine and camphor as before. To square up glass tubes, put them on a hard wood mandrel made by driving iron rod with centers through a block of cherry, chestnut or soft maple, and use the flat of a single cut file in the tool post, wet as before; run slowly. Large holes may be rapidly cut by a tube-shaped steel tool like a file on the angular surface, or with fine teeth, after the manner of a rose-bit, great care being necessary, of course, to back up the glass fairly with lead plates or otherwise, to prevent breakage from unequal pressure. This tool does not require an extremely fast motion. Lubricated as before, neat jobs of boring and fitting glass can be made by these simple means. The whole secret is in good, high steel, worked low, tempered high, and wet with turpentine standing on camphor.

DEATH FROM CARELESSNESS.—Two instances within a week have been reported of men being killed while walking on railroad ties in the East. One of the victims was so deaf that he could not hear the approaching train. The other was reckless enough to take the chances of being run over. Both suffered death for their temerity. Some people will never gain wisdom, nor profit by the experience of the past. So it is with those who snap guns and pistols at others, in the belief that the weapons are not loaded, and discover how fatal has been their error when they see that the person aimed at has been killed. And so, also, with those who pull loaded guns from wagons, with the muzzles toward them, and receive the contents of a discharge in their bodies. These fatal accidents are recorded by the press as items of current news, but not with the expectation of always preventing them. This same sort of incaution has been the subject of notice time out of mind, and will probably continue through generations to come.

TO CLEAN GLASS AND SILVERWARE.—Eggshells crushed into small bits and shaken well in decanters three parts filled with cold water will not only clean them thoroughly, but make the glass look like new. By rubbing with a damp flannel dipped in the best whiting, the brown discoloration may be taken off cups in which custards have been baked. Again, all of us are aware that emery powder will remove ordinary stains from the white ivory knife-handles, or that the luster of morocco leather is restored by varnishing with the white of an egg. Nothing, it is said, is better to clean silver with than alcohol or ammonia, finishing with a little whiting on a soft cloth. When putting away the silver tea or coffee pot which is not in use every day, lay a stick across the top under the cover. This will allow fresh air to get in, and prevent the mustiness of the contents familiar to boarding house sufferers.

PARAFFINE STOPPERS.—Mr. Kirster, a German pharmacist, has recommended, in the *Pharmaceutische Zeitung*, the use of paraffine in place of corks or other stoppers for the hermetic sealing of bottles containing liquids which are prone to ferment or otherwise deteriorate by coming in contact with the air. This, he says, is particularly applicable to syrups or saccharine juices of all kinds. They are poured, while hot, into perfectly dry bottles, which are filled nearly up to the lip. Then they are allowed to stand and rest until cold, during which time all air bubbles will rise to the surface. Finally, a small quantity of melted paraffine is poured over the top, when it forms a firm, solid coat on cooling, about the tenth of an inch thick. Such a paraffine stopper is easily removed when the contents of the bottle are required for use, and by collecting the paraffine it can be used again.

A TEA COMPANY'S INSTRUCTIONS.—"To make tea to perfection, boiling water must be poured on the leaves directly it boils. Water which has been boiling more than five minutes, or which has previously boiled, should on no account be used. If the water does not boil, or if it be allowed to overboil, the leaves of the tea will be only half opened, and the tea itself will be quite spoiled. The water should be allowed to remain on the leaves from 10 to 15 minutes." This is in a direct line with the Delmonico wisdom about the proper way to cook water, and its solemn warning that water which was boiled too long was loaded with mineral impurities and unfit to drink.

CURIOUS FACTS IN THE CONSUMPTION OF COPPER.—It is a curious fact, which is not widely known, that the heavy copper consumption of India is due largely to a religious rite of the natives. At certain seasons of the year small cups of sheet copper about an inch in diameter and an inch and a half deep are filled with rice, and are thrown into the rivers as an offering, with religious ceremonies. The quantity of copper thus annually consumed is very heavy, India sheets being an important article of commerce.

SOLUBLE GLASS AS A PRESERVATIVE.—Three coats of soluble glass, each applied at an inter-

val of a day, the *Pottery and Glassware Reporter* says, are sufficient to preserve porous materials indefinitely at a cost of about 15 cents per square yard. When applied upon old materials it is necessary to wash them thoroughly with water first. The degree of concentration of the solutions to be used varies with the materials. For hard stones the solution should mark 7 deg. to 9 deg. Baume; for soft stones with coarse grit, 5 deg. to 7 deg.; for calcareous stones of soft texture, 6 deg. to 7 deg. The last coating should always be with a dilute solution of 3 deg. to 4 deg. only.

THE WIRE FENCE AN OLD STORY.—The general public is under the impression that wire fences have only lately been introduced. This is a mistake, for as far back as 1816 fence wire was manufactured by White & Hazard, at the Falls of Schuylkill, near Philadelphia. A letter from this firm, dated January 2, 1816, is in existence, addressed to Richard Peters, President of the Agricultural Society, recommending wire fencing, and an elaborate calculation was given to show the economy there would be in the adoption of such a durable material in place of perishable posts and rails.

PAPER FOR WRAPPING OF SILVER.—Six parts of caustic soda are dissolved in water until the hydrometer shows 20 B. To this solution are added four parts of oxide of zinc, and boiled until dissolved. Sufficient water must next be added to reduce the solution to 10 B. Next dip paper or calico into this solution and dry. This wrapping will very effectually preserve silver articles from being blackened by sulphuretted hydrogen, which, as is well known, is contained in the atmosphere of all large cities.

CLEANING POWDER FOR SHOW WINDOWS.—A good cleaning powder which leaves no dirt in the joints, etc., is prepared by moistening calcined magnesias with pure benzine, so that a mass is formed sufficiently moist to let a drop appear when pressed. The mixture is to be preserved in glass bottles with ground stoppers, in order to retain the easily volatile benzine. A little of the mixture, when to be used, is placed on a wad of cotton and applied to the glass plate. It may also be used for cleaning mirrors.

STRANGE BUT TRUE.—This is one of the curious things floating about. Take a piece of paper, and upon it put in figures your age in years, dropping months, weeks, and days. Multiply it by two; then add to the result obtained the figures 3768; add two, and then divide by two. Subtract from the result obtained the number of your years on earth, and see if you do not obtain figures that you will not be likely to forget.

INSOLUBLE CEMENT FROM GLUE.—In order to render glue insoluble in water, even in hot water, it is only necessary, when dissolving glue for use, to add a little potassium bichromate to the water, and expose the glued part to the light. The proportion of bichromate will vary with circumstances; but for most purposes about one-fiftieth of the amount of glue will suffice.

GOOD HEALTH.

Flies and Their Relation to Disease.

It is a common belief that the absence of flies for a season is a precursor of an epidemic. The process of reasoning on this subject is given substantially as follows, by a writer more rational than superstitious, which we find in the *Midland Industrial Gazette*. The absence of flies does not exactly preface an epidemic—that is, the flies are not killed by the poison in the air, as many superstitious persons who have noticed the coincidence between disease and a small fly crop believe—but their absence is in itself a cause of sickness and epidemics. The fly is a vulture, a buzzard on a small scale. It is the most important, because the most numerous destroyer of pest-breeding material. It gets in on foul and decaying matter that can be reached by no other insect or animal, and destroys it. The quantity of this pestilential matter thus removed cannot be estimated, because the fly is always getting away with it in summer, while in winter the cold prevents its evil influences being felt. When, therefore, there are too few flies to thoroughly consume all the forms of the dead and decaying substance that fills the earth, the surplus pollutes the air, the soil and water, and creates and propagates disease.

In contradistinction to the above, Doctor Grassi, in an article in the *British Medical Journal* in 1883, on danger from flies, claimed to have made an important and by no means pleasant discovery in regard to flies. It was always recognized, said the learned Doctor, that these insects might carry the germs of infection on their wings or feet, but it was not known that they are capable of taking in at the mouth such objects of the ova of various worms, and of discharging them again in their feces. This point has now been established, and several striking experiments illustrate it. Dr. Grassi exposed in his laboratory a plate containing a great number of the eggs of a human parasite, the *Tricocephalus dispar*. Some sheets of white paper were placed in the kitchen, which stands

about 10 meters from the laboratory. After some hours, the usual little spots produced by the feces of the flies were found on the paper. These spots, when examined by the microscope, were found to contain some of the egg of the tricocephalus. Some of the flies themselves were then caught, and their intestines presented large numbers of the ova. Similar experiments with the ova of the *Oxyuris vermicularis* and of the *Tenia solium* afforded corresponding results. Shortly after the flies had some mouldy cream, the *Oidium lactis* was found in their feces. Dr. Grassi mentions an innocuous and yet conclusive experiment that every one can try. Sprinkle a little lycopodium on sweetened water, and afterward examine the feces and intestines of the flies; numerous spores will be found. As flies are by no means particular in choosing either a place to feed or a place to defecate, often selecting meat or food for the purpose, a somewhat alarming vision of possible consequences is raised.

SWISS TREATMENT OF CONSUMPTION.—An interesting report is given of the experiments made by Dr. Albrecht on consumptive patients in a hospital at Berne, Switzerland. These experiments were made with a view to ascertaining the effect of oxygen inhalation upon the development of phthisis, and whether by increasing the rate of organic combustion by this means the bacterium of phthisis had been discharged with certainty on several occasions. The patients were first submitted to an appropriately high nutritious diet, consisting of milk and peptone, and twice a week they were weighed with great care. It was observed that, as soon as the oxygen inhalations began, the daily loss of weight was checked, and in some cases the weight increased, dyspnea diminished, and the microscope showed fewer bacteria.

CIGARETTE SMOKING.—Cigarette smoking has become such a general nuisance, says a New York letter, that small signs have been printed and kept for sale, which read: "No smoking allowed in this office." A man who sells these says: "The greatest demand for them comes from the banks. The young men who make deposits and carry messages for business firms are mostly all addicted to the vice of smoking cigarettes. There is something about the smell of burning paper and poor tobacco that is excessively annoying to some men. It is almost poison to them, and I found that when I began printing these cards they had a ready sale. Now nearly every bank, lawyer's office and railroad office has one of them prominently displayed. If I could have patented the idea, I might have made a fortune out of it."

TEMPERATURE OF ROOMS.—The ventilation of rooms in which human beings must remain hours at a time is a very important matter. Separate rooms can only be kept anywhere near reasonably ventilated by raising the window-sash one inch from the bottom and lowering it a like distance from the top. By this means the air in the room is constantly renewed and drafts are avoided. In the sitting-room, see that the mercury remains about 70 degrees, rather below than above this. In the sleeping apartment 60 degrees is a very comfortable temperature. A higher degree of heat than this would be quite admissible where there are young children.

NERVOUS TOOTHACHE.—For ordinary nervous toothache, which is caused by the nervous system being out of order or by excessive fatigue, a very hot bath will soothe the nerves that sleep will naturally follow, and upon getting up the patient will feel very much refreshed and the toothache will be a thing of the past. For what is known as "jumping" toothache, hot, dry flannel applied to the face and neck is very effective. For common toothache, which is caused by indigestion, or by strong, sweet acid or anything very hot or cold in a decayed tooth, a little piece of cotton steeped in strong camphor or oil of cloves is the best remedy.

TREATMENT OF BOILS.—Halle recommends the following application in furuncle: Tannic acid, one part; powdered gum acacia, one part; tincture of arnica flowers, two parts. This is to be painted over the boil and for a little distance around it, several coats being applied until it forms a thick and firm covering. Halle states that this mode of treatment quickly relieves the pain and diminishes the swelling. When taken in time the boil disappears without the formation of pus; and when this has already occurred the application causes the extrusion of the core and prompt healing of the furuncle.

A VALUABLE INVENTION.—Edward Keeler, of Hokah, Minn., has invented a device to prevent accidents from people having their feet caught in the frogs of railroad tracks. The device consists of a piece of steel, so curved as to fit tightly in the crevices in the frog.

FOR ERYSIPELAS.—Dr. Sydney Thompson suggests the following formula in erysipelas: Fluid extract of jaborandi, twenty-four parts; laudanum and glycerine, each four parts. This mixture is to be painted over the affected surfaces every four hours.

GLYCERINE IN ACUTE NASAL CATARRH.—Cotton saturated in glycerine and introduced into the nares relieves the congestion at once.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

SUTTER CREEK.—Amador Ledger, Oct. 21: I have to report this week the closing of the Eureka or Amador Consolidated mine. They have been prospecting for six or seven years without any development of importance. Supplies of all kinds were exhausted, and winter close at hand; something had to be done. Last week word was sent from below to stop work. Only two men are kept for the purpose of keeping out the water. Matters are likely to remain this way at least until a meeting of stockholders is held. At the Lincoln only two or three men are employed, owing to the scarcity of water. They have plenty of ore, and it is said to be of paying grade. The stamps of the Iowa are also idle, waiting for rain. The Mahoney remains at ease, with the long expected operators still invisible. The Red Cross mine, situated about six miles east of here, was brought to a standstill a few days ago. The hands are manifesting some anxiety about their wages.

Kern.

THE TEHACHAPI MINES.—Kern Co. *Californian*, Oct. 21: We received a call this week from P. D. Greene, one of the oldest and best known of the residents of Tehachapi, who gave us some interesting facts respecting the mining interests of that part of the country. He estimates the number of distinct gold-bearing leads, which have thus far been found at not far from 20. They are located in the mountain chain that forms the southern boundary of the great depression in the Sierras, known as Tehachapi Pass, not far from the summit. The principal one, which is of great size, known as the Pine Tree, has many claims located upon it and affords ore of about uniform quality along an extent of a mile and a half. These claims, or several of them, have been profitably worked, without penetrating to any depth to speak of, for three years, and lately the lead has attracted the attention of parties from abroad who have bought interests, paying considerable sums for them. The ore is decomposed and taken out without blasting. Two tunnels are being run to strike the vein at a great depth, one of them having been pushed the distance of 400 feet. If the lead is found of the size it is on top and carrying the same amount of gold the owners will feel assured that they have a property of great and permanent value and the owners of those more recently discovered will be encouraged in the same degree. Mr. Greene feels confident that these leads will be found just as good, if not better, at great depths than on the surface, because the formation is similar to that in which the most noted mines in Amador county are situated. One of the recently discovered leads is as large as the Pine Tree and the ore is about the same grade. The rest are smaller, but some of them richer. Below these leads, at the edge of the plain, are placer diggings which have been worked to a greater or less extent since 1856, which evidently derived their gold from them and are a favorable indication of their value. Three mills are in operation; one of them was erected to do custom work. The miners and prospectors on the ground are quite numerous, and all busy and full of hope. But new life will be infused into operations if the tunnels make good strikes. Then more mills will go up, and one of the liveliest mining camps result which this country has ever had.

Mono.

STANDARD CON.—Bodie Free Press, Oct. 24: The retimbering of shaft continues favorable. Ore shipped to mill 323 tons. Bullion valued at \$10,525 shipped on Tuesday 20th.

MONO.—The drift south from No. 1 winze 550 (Lent shaft) level is in 80 feet. We find good ore in this drift. Fifteen men employed.

BODIE CON.—At the Bodie mine the report for the week is as follows: The east crosscut 700 (Lent shaft) level, is in 121 feet. North drift No. 1, 400 (Mono) level, is in 20 feet; north drift No. 2, same level, is in 128 feet. The joint upraise on same level, is up 102 feet. Thirty men employed.

CON. PACIFIC.—Since last report winze No. 2 has been sunk to a depth of 27 feet. Will resume work in winze No. 1, next week, and will connect the two for air, at or near the 50-foot level.

Nevada.

NORTH STAR MINE.—Grass Valley Union, Oct. 21: The North Star mine is beginning to justify the expectations of those who reorganized the company and put the mine again on a working basis, and at the present time there is a steady output of ore from various levels as tribute and company rock, and the yield is very satisfactory. Since the first of the present month, the ten stamps of the Larimer mill, which is under lease to the company, have been running steadily upon the rock, and the intention now is to put a force in the mine that will supply the full head of twenty stamps constantly with ore. Two clean-ups have been made since the mill started, for two weeks' run, the yield being \$6400, and the total for the month will be sufficient to leave a handsome margin of profit over expenses. This is doing very well for an old mine that the former company considered was worked out, and who shut it down for want of pluck in expending sufficient money for needed development. There is every probability that the North Star will again yield as profitably as at any time in its previous history.

MANZANITA GRAVEL MINE.—Nevada Transcript, Oct. 24: Superintendent Gowell of the Manzanita gravel mine in the northern edge of the town went below recently for the purpose of endeavoring to make arrangements for working the claim extensively by the drifting process. Two of the heavy stockholders are widows, and it is necessary to secure their consent before going ahead. Just after his arrival at the Bay, Mr. Gowell was taken sick, and this has delayed negotiations, but he is expected back here soon with authority to begin drifting. A number of men are now cleaning bedrock in the claim and getting considerable gold. All idea of further hydraulicking having been abandoned, the paving in the bedrock tunnel was taken up a short time ago, and quite a quantity of amalgam was realized in so doing.

THE COE MINE.—Grass Valley Union, Oct. 21: The Coe mine, situated at the head of Hill's Flat, on the Nevada road, has been bonded by the owner, E. W. Roberts, to George Murphy, in the interest of young John Robinson, the well known circus man. Mr. Robinson has already been engaged in mining prospecting here, and has so much confidence in the district that he is willing to make further investments. It is understood that the bond is only for a brief period, and that there was a cash payment upon the making of the agreement. The Coe was formerly worked with variable success under different ownerships, and although yielding good ore, and proving to be a strong vein, there was a good deal of unskilful underground work as well as false economy in the management, and thus, what was considered a meritorious mine by practical miners failed to be remunerative. The shaft is down 500 feet, but no stopping has been done at that depth. Under intelligent management and with such investment of money as the property will justify, there is no doubt that the Coe will prove a profitable gold producer.

Placer.

ANOTHER IMPORTANT DEVELOPMENT.—Placer Herald, Oct. 24: We learn from Mr. Jas. Laird, of Pmo, who made us a call Tuesday, that an important development has recently been made in the Geo. Lee mine, on the old Bradley place, east of Rocklin. It seems that Mr. Lee has been working off and on, on a gravel channel which is known to traverse that neighborhood, for some time, and with varying results. Not long ago he bonded his claim to a Mr. Burlston for 90 days. The latter at once put a force of men to running a drift up the channel. He has proceeded several hundred feet, and the gravel, from being one or two feet deep is now five or six feet deep, and is very rich, paying in some places nearly a dollar to the pan. Enough has been done to prove the existence of a big mine and a rich mine. That section has already yielded a great deal of gold, first and last, but Mr. Laird thinks there is \$100 there yet for every dollar that has been taken out.

FOREST HILL.—One of the main pumps in the famous Mayflower mine, near Forest Hill, gave out on Wednesday a week ago, which caused the mine to fill considerably with water, and seriously interfered with the work of taking out gravel. After working two days in the endeavor to repair the damages, it was finally concluded to put on bigger pumps and heavier machinery, and to secure these Superintendent Chappell went below last Saturday.

CRUSHING.—Placer Argus: The "Thirty-one mine," situated near Danville, was to have started work crushing rock last Monday. The mine, formerly owned by J. C. Crosby, is now run by a company of San Francisco mining men, who went to work energetically and spent several thousand dollars in erecting various works, including a ten-stamp mill.

PLACER'S MINES.—An item is going the rounds to this effect: "Placer county is having quite a boom in mining matters." This is true. Placer's drift and quartz mines never promised better. Some think from present indications that the gold yield of this county for the current year will exceed the yield of any other county in the State. The channel on the Forest Hill divide, recently located by developments in the Mayflower, contains as much wealth, doubtless, as ever came out of the Comstock, and Forest Hill to-day is one of the liveliest mining towns on the coast.

Shasta.

THE RICHEST YET.—Republican Free Press, Oct. 20: We were shown this morning a veritable curiosity in the shape of a mineral deposit. It was simply a conglomerate mass of lava, quartz and gravel, interspersed with bunches of gold particles about the size of and resembling large grape seeds. Mr. John O. Welsh, who showed us the specimen, says that it came from near Mt. Shasta, and was found about 40 feet from the surface. The discovery is called the "Great Northern Boom," and is the richest yet made, there being acres of this rich strata. There is much excitement regarding this new field of wealth.

NOTES.—Shasta Democrat, Oct. 21: A new pump for the Clark mine at Quartz Hill was taken to the mine yesterday. McCusick, ex-Postal agent, returned here Monday evening on a visit to the mines. We are told that fully 150 men are employed by the Iron Mountain mining company. Mining men are as thick as usual, and we hear several rumors of prospective sales of mining properties. Capt. Vincent, a commercial man, has bought an interest with "Wild Bill" in a quartz claim on China gulch. Dan O'Neal is running his cannon-ball mill on excellent rock taken from the first extension south of the Florida. Whitton & Bassett are running their horse arastra on their Squaw creek mine night and day on ore that averages over \$100 to the ton. Andy Eide and Andy Tilden have out 60 tons of fine ore from their mine on Salt creek and will have the same crushed in Merithew & Co.'s mill at Lower Springs. Hon. Reuben Clark returned to Colusa county last Friday morning, and yesterday evening one of his partners, Mr. Marshall, came up to take charge of the mine and mill at Quartz hill. Mr. Elijah Hickman of Tehama county has discovered a fine body of asbestos in this county, and yesterday went to Shasta and recorded his claim. Mr. Minear, proprietor of the Wiley mine at Deadwood, was in town Friday and Saturday last. He gave a good report of the district in general and says he is doing quite well with his property. He is running a long tunnel to tap the vein several hundred feet deep, and 150 feet more will finish it. A very rich gold quartz vein was recently struck on Jerusalem creek, within a few miles of Bullychoop, by an old prospector named Wheeler, which he has bonded to a company for \$10,000. The vein averages about two and a half feet in width, and we are told every pound of the ore prospects big in free gold and carries a heavy per cent in rich sulphurets. Jack Conant last week effected a sale of one-half of his group of claims on Squaw creek for \$50,000 to a New York company, and the deeds of transfer were filed in the clerk's office last Thursday. The purchasers are said to be a Mr. Reilly of the celebrated Copper Queen silver mine in Arizona, who has made several visits to the county this last summer, and a New York banker, the business having been transacted through a Mr. Matthews, a mining expert, who is at present at Redding. From Mr. Morse, who was up in the lumber regions of Pit River last week, we learn that a four-foot vein of coal was recently discovered near Buzzard Roost. The coal has been tried in a blacksmithing forge and for that purpose does as well as the best. It is the intention

of the parties making the discovery to develop it. As yet they do not know the extent of the deposit. This is the second discovery of coal in that part of the country.

NORTHWESTERN SHASTA.—Cor. Shasta Courier, Oct. 24: We are compelled to say that Sunny Hill mining district has received what we call a blackeye. That very rich company that lately bonded the Spencer lead, at a fair price, after having prospected the mine to their entire satisfaction, have thrown the enterprise up, and pronounced the mine a failure. Mr. Oats, Tim Quinn's "Flower of Sunny Hill" man, has struck his ledge by a tunnel of about 140 feet in length—the ledge is 14 inches in width, but of low grade ore. The vein shows permanency—being in terrible hard country rock. Levi Davis' mine, which was bonded to Spencer, a short time since, is a ledge of about 30 inches in width, and will mill \$100 per ton. In Bullychoop affairs continue encouraging, but Messrs. Potts, Foster, Finch & Co., are doing nothing at present on the Cumberland. That company have paid out a great deal of money this season, in completing the new toll road into Bullychoop, and it is quite likely, owing to the hard times, that they will not do much until another season. Prospects in the Big Central continue favorable, and the company are still taking out good milling rock. The Haskins and Enright Company are pushing their works ahead. The pending lawsuit between them and the Bullychoop Company have given them a little backset. Jasper Davis and brothers, are at work, and these hard-working boys has done a great deal to prove that the mines of the Bullychoop have "roots" for they have gone deep into the bowels of old mother earth and have found their ledge larger and richer than it is on the surface.

Sierra.

PRIMROSE.—Sierra Tribune, Oct. 20: The mine is situated pretty well up at the head of Hog canyon about five miles from Sierra City and on a range with the Sierra Buttes lead. The Primrose is one of the pioneer quartz mines of this county and during the time it was worked ranked as one of the most valuable. Since 1865 not a pound of ore has been taken from the Primrose chimney. However, at a later date a new shaft was sunk down 200 feet on another part of the claim and a tunnel started, which would tap the pay chimney about 150 feet below the old workings. This tunnel has been worked upon at different periods, until now it is in 1400 feet, and is undoubtedly very near the pay chimney. Taking the pitch of the vein where it was worked in former years, it is reasonable to believe that the tunnel will reach pay in 50 feet. The mine is very pleasantly situated and is on a good mineral belt. There is a fine water right connected with the property and any amount of timber close at hand. The milling facilities consist of one 12-stamp mill, having a reduction capacity of 24 tons in 24 hours. The machinery is so regulated that one engine furnishes power for the pumping and hoisting machinery as well as the stamps, and runs the whole with perfect ease. The drain tunnel is some 600 feet in length, and intersects the shaft 50 feet below surface, thus obviating the necessity of pumping water above that level. The mine is at present being operated by a company incorporated in Alameda county last June. They are making preparations to get a new pump, drain the shaft and then drive ahead the tunnel to the old Primrose chimney, which proved so rich in former years.

A LONG TUNNEL.—No. 9 tunnel, at the Sierra Buttes mine, is now in 6200 feet by actual survey. An upraise is being put through from this tunnel to No. 8 tunnel, which is 750 feet higher up.

STRINGER.—T. L. Flannigan was here from below last week looking after the Mead quartz claim, which has recently been purchased by him. The mine is situated in Hog canyon. Sam Baker was sent up there by the new owner to clear out the tunnel and do some other work.

Tuolumne.

LOCAL NOTES.—Sonora Democrat, Oct. 24: It is likely that the Hyde mine will be sold to San Francisco parties in a few days. Parties have recently been looking at the Eureka mine, Summersville, with a view to purchase. It is reported on good authority that \$500,000 was offered and refused for the Buchanan mine last week. The Kanaka mine at Groveland, was sold at Sheriff's sale last Saturday. W. R. Shaw was the purchaser, buying the mine in for \$5100. The Lamphier mill started up last Saturday, with a four months run of rock on hand. The chute in the south ground is showing up finely, the rock being stoped from it averaging \$30 per ton. We learn that the Italian or Onesti mine at Deer Flat, near Groveland in this county, has been bonded for 30 days to parties in San Francisco at good round figure—considerably in advance of what it was formerly held at—with every reason to believe that it will be sold. This goes to show the revival of quartz mining, which this county is sharing in common with all other mining counties of the State, and we can justly say that this county affords as fine a field for the judicious expenditure of effort and money in this line as any county in the State. Its past record and present indications prove this. This mine has been repeatedly brought to the attention of capitalists during the past year by Mr. Louis Blanding, who is now here, after a thorough examination of the mine and numerous tests made of the ores in his own mill in San Francisco and also in the 10-stamp mill on the ground—and he has always stated his decided opinion of its great value, and urged parties to investigate it for purchase. The present negotiations for its purchase were based upon a recommendation of the character and value of the mine made by Mr. Blanding to a gentleman here, who though knowing nothing of the mine personally, was induced by the full description and representations given him by Mr. Blanding to state his favorable impression of its merits and recommend action to the parties in San Francisco, making inquiries of him concerning it.

TELLURIDE.—Tuolumne Independent, Oct. 24: While testing some ore substituted to him yesterday from a vein in the vicinity of this town (Sonora), Mr. Louis Blanding discovered the presence of petzite, one of the forms of telluride of gold, and that it existed throughout the ores of the mine in paying quantities—even the snow-white quartz, though showing not a single indication of mineral or free gold, under a powerful glass, yielding the telluride in small quantity and many of the samples a very considerable percentage. The telluride was concentrated, but not closely, and gave by three separate tests made for verification, the extraordinary large result of \$60,000

per ton in gold—the silver in the ore not being estimated. The ore yields readily to treatment. This and other forms of telluride of gold has been found in Shasta, Sierra, Amador and Calaveras counties, and now Tuolumne county must be added to the list. This ore is the most valuable form of gold ore known to exist.

Trinity.

MORE QUARTZ.—Trinity Journal, Oct. 24: Mr. Nelson Waite tells us that Maxwell & Matthews have recently discovered a four-foot ledge on Squirrel Creek, about seven miles from Trinity Center, which prospects big. There is no free gold found, but the sulphurets are very rich, and the estimates place the rock at \$60 or \$70 per ton. Mr. Waite has several locations in the same neighborhood which show up well. The quartz is black and prospects favorably in free gold.

NEW RIVER.—Cor. Journal: New River still survives, and prospects were never better than at present. There is a scarcity of water which makes crushing ore with arrastras slow work. Messrs. Ladd & Clement are running through some very rich rock at present. They have two arrastras running—one on the Hard Tack and one on the Mountain Boomer. The Tough Nut arrastra started up this morning and will run steady from now on, Mr. Levasseur having opened up the mine in good shape. The Ridgeway Co. made a handsome clean-up, much better than they expected, as they were running on second-class ore. The Buckeye Co. struck a twenty-inch ledge on their lower level. This is one of the most promising mines in the district. The Uncle Sam mill will start up this week under new management, and no doubt will be a success, they having struck a winze on the lower level and struck a two-foot ledge of good ore. The Golden Gate is showing up in fine shape as are several others too numerous to mention. Several mines are lying idle waiting for water.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Enterprise, Oct. 24: There is but little to be said in the way of improvement developed on the 3100 level. The advancement of crosscut No. 3 west continues suspended in order to promote other operations, but will be resumed in a day or two. This crosscut is in about 13 feet, and is a pretty important matter, being 40 feet south of the deep winze and in good ore, which evidently extends southward, and should be intercepted by the two crosscuts further south. Crosscut No. 2, 90 feet from the Chollar north line, is now in about 50 feet in a good solid quartz vein formation, carrying streaks and bunches of ore in its face, some of which give high assays. It is being turned a little more to the northward. Crosscut No. 1 at the Chollar line, is in about 60 feet, and shows strongly mineralized quartz. On the 3000 level the crosscut west from the north lateral drift and about 50 feet south from the face, is now in about 20 feet in a heavy dry clay and quartz formation. Work will be resumed in the face of the north lateral drift Monday, advancing it towards the Savage line, which is something over 100 feet distant.

CHOLLAR.—Crosscut No. 1 west on the 3100 level, being driven jointly with the Hale & Norcross Co., is in about 60 feet in a strong, pure quartz formation. Work has been resumed in the southwest drift, from the main Combination west drift. This will explore the Chollar ground on that level very advantageously, its course taking it diagonally across the ledge to the west wall, which it is expected to reach in a distance of 150 feet. The completed hydraulic pump in the Combination shaft works perfectly with an abundance of reserve power, and giving the Cornish pump little or nothing to do. Quite a force of men under the management of Captain J. B. Overton, Superintendent of the Water Company, are employed in the old upper workings of the mine, preparing for the extraction of ore from that section. Some hundreds of tons which were extracted last spring, have recently been shipped to the Eureka mill, on Carson river, for reduction.

CON. CALIFORNIA AND VIRGINIA.—About 500 tons of ore were raised during the week from the 1750 level on company account, assaying \$24 per ton. About thirty men are employed in the Jones lease section, between the 1300 and 1400 levels, preparing better facilities for ore-extraction when an increase of water in the Carson river shall furnish the requisite motive power to run the Eureka mill. Considerable improvements have been and are being made at the surface works of the old Consolidated Virginia shaft, and a new building is about being erected over the hoisting works.

SIERRA NEVADA.—Work is suspended in the face of the crosscut west on the 520 level, 1000 feet north of the shaft; 436 feet is the full extent of this crosscut from the main lateral drift, and the material in its face indicated proximity to the west wall of the lode. At a point in this crosscut, 250 feet west from the main north lateral drift, a drift has been started north during the week in a favorable quartz-streak, which had been passed through. This drift is already in 30 feet from the crosscut, the material is fully one-third quartz, carrying streaks and bunches of low grade ore.

CROWN POINT.—Sufficient ore is being extracted from this mine and the Belcher to give the Mexican, Vivian and Santiago mills what their present limited capacity will allow them to crush, which, in the aggregate, amounts to about 160 tons per day. The old upper workings of Crown Point still show large amounts of low-grade ore. That from the Belcher is of higher grade, and comes from the 1750 level, above the water surface.

YELLOW JACKET.—About 170 tons continues to be the daily yield from the 1300 level and above. There is a vast amount of low-grade ore in the mine, and while regular extraction goes steadily along, keeping the Bunsnick mill well supplied, considerable prospecting work is being done in the upper portion of the mine, and also on the 1700 level through the Crown Point and Kentuck, above the water level.

UNION CONSOLIDATED.—On the 500 level the crosscut west from the main lateral drift is in a little over 100 feet. Face in vein porphyry and favorable looking quartz. The crosscut east on this same level, 100 feet south of the Sierra Nevada line, also shows very promising vein matter in its face.

OPHIR.—The main drift west on the 400 level continues passing through vein matter on its way to the west wall. The ore known to exist above this drift

will be stoped out by means of upraises. The ore house at the hoisting works has been repaired to receive it.

GOULD AND CURRY.—Crosscut No. 1 west at the Savage line, is now in 550 feet, having been advanced 46 feet during the week. Its face shows no change, being in the same material as last week—hard, dry vein porphyry, with an occasional streak of quartz.

BEST AND BELCHER.—On the 1000 level crosscut No. 2, west, 100 feet south of the old Consolidated Virginia line, is now in 336 feet, having been advanced 42 feet during the week. The face continues in vein porphyry, clay and quartz.

MEXICAN.—The middle crosscut east on the 500 level is being advanced at the rate of over 50 feet per week. The formation is heavy clay, vein porphyry and quartz, the whole looking favorable for the finding of an ore body.

KENTON.—Nothing new. Extracting the usual supply of ore from the old upper workings to keep the Rock Point mill steadily running.

ALTA.—The west drift on the 700 level makes steady and good advancement, and less than 100 feet further will carry it into the ore body.

Aurora District.

THE ENGLISH CO.—Walker Lake Bulletin, Oct. 24: Every now and then somebody interested in Hawthorne district complains that too much has been said about some property situated there. Every now and then somebody interested in the same place complains that too little has been said. The people of Aurora are just as bad as the operators in Hawthorne district. Those who have good information keep it until they can derive a benefit therefrom, and then want plenty of news spread to suit their own views. Those whose interests are the reverse wish the world to believe an entirely different story, and it is only by looking at the signs of the times and patching up a fabric from stray pieces of information that any idea of the exact situation can be obtained. As it is, judging from a few hints, as to date, derived from anxiety to have some other transaction completed at a certain time, and from the action of those apparently best informed, it seems pretty safe to say that the English company is making arrangements to begin operations in Aurora on or about the first of December.

Columbus District.

MOUNT DIABLO.—Candelaria True Fissure, Oct. 24: The incline has been sunk 20 feet during the week. The east drift on the sixth level is in 156 feet, and the west drift on the same level has been driven 10 feet during the week. The east intermediate drift from the winze connecting the fifth and sixth levels, has reached a length of 59 feet, while the west drift from the same winze is in 45 feet, and shows considerable ore, assaying about \$25 per ton. The east and west drifts on the fifth level show no change. The upraise from the intermediate, between the fourth and fifth levels, has attained a height of 44 feet, and shows from 8 to 10 inches of \$75 ore. The winze from the east drift, on the fourth level, is down 27 feet and shows favorable ground for ore. The east drift from winze No. 7 is in 45 feet and shows ledge matter with some low grade ore. The raise from the east drift on the second level is up 28 feet, and shows a few inches of \$40 ore.

Hawthorne District.

ANOTHER RUN.—Walker Lake Bulletin, Oct. 20: The Cat Creek mill, after having crushed about 20 tons of Lapanta rock, was again obliged to shut down for lack of water. The bar resulting from the clean-up last Saturday is valued \$1640, over \$80 to the ton. This is a pretty good return, as the rock worked was second-class. There is about the same quantity still at the mill which will be worked as soon as the water supply permits.

DO SOME WORK.—Everybody is putting up monuments and locating new claims, in the meantime but little work is being done in Hawthorne district. Those who have their mines opened are making money, but those who sit and wait for a purchaser will be likely to wait a long time. In many claims a few good mines will be discovered and the fortunate owners will get rich, and it is better to know whether a claim is worth holding or not; it is better to work it and learn that it is worthless, than to waste time sitting on a location monument waiting for a sale.

Patterson District.

ORE.—White Pine News, Oct. 20: Wm. Warmath, an old Treasure Hill miner, but now in Patterson district, has been in town several days looking for Mormon teams to haul ore to the railroad, either to Frisco or Deseret. From him we get the following particulars in regard to that district. Several locations are being worked and all give promise of proving valuable properties. Mr. Warmath, and John Kreiner are working the Saratoga and Viola, and have out quite a quantity of ore that assays from \$700 to \$700 to the ton. Messrs. Flowers and Peterson, both Hamilton men, are working the Victoria, Bender, and Great Western, and also have a quantity of fine ore awaiting shipment. The Mathewson Bros. own the Grey Eagle and several other locations upon which work is being done. Mr. Warmath believes that if a railroad came within any reasonable distance of Patterson that district would show up as a good bullion producer.

ARIZONA.

PINAL MOUNTAIN MINING NOTES.—Arizona Silver Belt, Oct. 24: From present indications the Pinal mountains are likely to become the best gold producing sections in this district, and to the limited amount of work done, the mines are showing up unusually well. Another good strike was made on the Cleveland mine, owned by Koons & Johnson, last week. The cut is about 16 feet long by 14 feet deep, and shows an ore body of 10 to 14 inches in thickness all the way down. Cut No. 1 is about 40 feet deep, and shows a fine body of native gold ore in the bottom. They have about 1½ tons sacked upon the dump and expect to have five tons ready to mill in a couple of weeks. This company also own the Hendricks claim, which is an extension of the Cleveland, as well as several other good claims near there. The Buena Vista, which is a farther west extension of the Cleveland, is owned by Ochs, White & Co., and is showing up extremely well. The main shaft is down 40 feet; the ledge is 11 to 14 inches wide all the way down, showing well in gold and silver. These parties have cut the ledge in different places, with the same result—each one showing that

the ledge holds out the full length of the claim. They have about five tons of ore on the dump, and intend building an arrastra. One peculiar feature of these mines is the ease with which they are worked; the formation is soft granite, full of slips, and so far has required no powder to blast, but yields readily to the pick and gad.

COLORADO.

LAKE COUNTY MINES.—Leadville Herald, Oct. 21: Dr. S. G. Canfield is working a profitable mine at Alicante, under a lease. The White Cap mine, of the Iron Hill consolidated group, is shipping some very fine ore. Mr. Crowe, as manager for Mr. J. L. Laws, will start up work in a few days on the Montana lode, on Fryer Hill. Mr. Joe Newton has taken a sub-lease on the Four Per Cent lode on Fryer Hill, and is now engaged in putting up a small steam-heating plant. Mr. Charles Pison is working a portion of the Catalpa mine under lease, and by prospecting the ground hopes to open up paying bodies of ore. The Blue Bird, on Sugar Loaf, leased to Wright Brothers, and the Stormy Lode, in the same vicinity, leased to Mr. Wilson, started up work in the past few days. The Amity lode, on Sugar Loaf Mountain, under lease to Messrs. Cohn & Truman, sent ten tons of fine ore to the Leadville smelters last week. The mine is owned by Mr. George O. Keeler. Mr. George A. Jenks has secured a two years lease on the Buckeye lode, situated on the north side of Fryer Hill. Two sub-leases have lately been let and the property is now being actively worked. Mr. Maxwell, who has a lease on the northern portion of the Amie lode, has placed a hoister on No. 5 shaft and is now engaged in straightening out a drift, preparatory to the extraction of ore. The hoisting engine on the Flagstaff shaft, on the north side of Iron Hill, was started up yesterday. Major Wilson and others have a contract to sink this shaft to mineral for a half interest in the lode. Mr. Finn, who has a lease on the extreme northern portion of the Chrysler property, has begun driving a shaft to the eastward. The drift is 82 feet from the surface and following a large body of iron ore. The purchases of ore in this district by Mr. Will Thompson, agent of the Pueblo smelter, during September, amounted to 4200 tons, of which 3700 tons were silver and lead ore and 500 tons silver-bearing iron ore. The Iron-Silver Mining Company, it is generally understood, has abandoned the project of moving the product of its mines by rail, and will continue employing about fifteen teams in the transportation of ore to the smelters. Messrs. Ward & O'Neil, who are working the lower portion of the Catalpa lode under a lease, are meeting with success. About ten days ago they started a new shaft, which, at 15 feet from the surface encountered a body of iron ore of value.

A diamond drill will be moved up to the Patrick shaft, on the Queen Consolidated, on Yankee Hill. The machine will be in operation in a few days, and it is to be hoped will prove more effective and economical in exploring the ground than a shaft with an uncontrollable flow of water.

IDAHO.

MORE GOLD IN THE BIG COPPER.—Houston Press, Oct. 21: Our prediction that this camp will eventually become a gold camp is rapidly proving to be a truism. In addition to the news of new and rich finds of gold quartz in several of the rock bound canyons that trend toward Houston, word came down to-day that another rich gold strike has been made in the Big Copper. The new find is nearly a thousand feet from the place of first discovery and there is every indication that the same ledge has been again tapped. If this theory proves to be correct who can estimate the vast amount of wealth that lies hidden within this mammoth ledge, 27 feet in width by 1000 feet in length and carrying from \$40.00 to \$204.00 in gold to each ton rock.

DOING BETTER THAN EVER.—Wood River Times, Oct. 21: The Queen of the Hills shows more ore than ever; the Climax is showing a bonanza; the Idahoan is yielding enormously; the Narrow Gauges are doing better than heretofore; the Cyclops and Red Cloud are showing a vast quantity of ore; the Pureka is about to be worked again; the Bay State group is doing well; the Homestake Fraction is showing rich ore; the Navaug and Bullwhacker are making regular shipments, while three or four other mines in their immediate vicinity will soon yield shipping lots of ore; on the Gold Belt the reducing capacity is being trebled and will doubtless be enormously increased in the spring; while the Smoky claims are turning out to be very rich and steadily produce ore in carload lots. All the above are mines directly tributary to Hailey. They are doing better than ever, and justify the prediction that time will be quite lively here next year, if Congress does not give silver "a black eye."

ANOTHER MILL.—Wood River Times, Oct. 21: Yesterday afternoon T. E. Ricotte, Idaho agent for the Wiswell mill machinery, received a telegraph dispatch from the works in Boston, stating that the mill just ordered for the Donovan group of claims, on the Camas Gold Belt, would be shipped next week. In 15 days from date of shipping, at the furthest the mill should be here. As Ole Rorem, who has charge of operations at the mines, will in the meantime have the grading completed and the building erected, and as the mill can be put together in three days, no delays should occur in starting. It is therefore safe to look for the starting-up of the mill by the 15th of November. If this mill works successfully, it will give a great impetus to the development of the Gold Belt, as it will be the second in successful operation—the experience of the Camas No. 2 Company having been so encouraging since it started up its mill, about three months ago, that it has already doubled the original number of stamps. Started up last July with 10 stamps, two more batteries of five stamps each are being put in place. This will give the Gold Belt an aggregate daily capacity of 50 to 75 tons. If, as there is every reason to believe, the works make a good all-winter run, there will be a positive boom on the Camas Gold Belt next year.

THE QUEEN OF THE HILLS.—Charles Popper, the principal stockholder in the Queen of the Hills and King of the Hills groups, arrived from New York yesterday, and laid over in Bellevue until this morning, in order to visit the Queen of the Hills. The Queen has been yielding 10 tons of first-class shipping ore the past eight months, that being the

capacity of the concentrating works; but Mr. Popper says that new works having a daily capacity of at least 40 tons will soon be erected, since there is no use in leaving so much ore idle as is in sight in the Queen.

MONTANA.

VARIOUS MINES.—Butte Miner, Oct. 21: The Late Acquisition, which is located on Montana street is worked by Messrs. Ed. Rodda & Co. A very rich ledge has been opened up and considerable high grade ore is being taken out. The Ophir, at the bottom of Colorado street, is being worked by its owners, and important developments are being made. Arrangements are being made to resume operations at the Gray Rock mine. At the Burlington considerable work is being prosecuted with the usual vigor and dispatch that characterizes the hard-working lessees, Messrs. Job, Madder & Co. The shaft is now down about 120 feet and cross cutting for the ledge at that point has been commenced. The stopes in the upper portion of the mine are producing large quantities of ore. The Magna Charta is running along in the usual smooth manner, and the stopes in the mine never looked better. The new hoisting works at the Elm Orlu mine is nearly completed, and a substantial plant of machinery is being put in place. The mine continues to look well and the usual quantity of ore is being extracted. The Moulton never looked better than at present, and there is no difficulty in supplying the mill with sufficient ore to keep it working. The Alice is producing well, and the supply of ore has been so great during the past few days that it was found necessary to lay off the miners a short time in order to give the great mills a chance to work off the surplus quantity of mineral that was piled up almost everywhere around the mines and mills. The Moose is looking well, and recent developments are of a very encouraging nature. It is reported that this mine will shortly pass into the hands of the Alice Co. Messrs. Stevens & Co., who are working the east end of the Rock Island on lease, are sinking the main shaft of that property with all possible dispatch. Tom Sturridge & Co. are working the western portion of the Rock Island, and are taking out considerable high grade ore. Messrs. Tretheway & Co. have given up their lease of the Annie and Ida mine at Walkerville, and that property is now worked by the original lessees, Messrs. Yount & Co., who speak very highly of the property. A large quantity of ore, going high in silver and gold, has recently been extracted from these mines. Messrs. Stoner & Co. are hard at work on the Blank Rock, and they are greatly encouraged in their labors by finding large quantities of good ore. The Narrow Gauge, in Deadwood gulch, is looking well, and large quantities of good ore are being shipped to the mills. At the Mount Moriah Messrs. Oatey & Co. are extracting considerable good ore. The mine is improving daily, and the lessees are very happy. Prospecting is the order of the day at the Union Consolidated mines, and the property is in a very encouraging condition. Some of the richest ore ever seen in this camp is being taken out of the Goldsmith. The mine looks splendid and is increasing in value daily. The Parrot mine was closed down a portion of last week, for the purpose of making some needed improvements to the machinery. The Fredonia mine, at Burlington, is rapidly coming to the front as a great ore producer. Messrs. Tom Rodda & Co. are working the mine on lease and are doing well. The Blue Bird is looking better than ever before, and an immense quantity of ore can be seen on the dump. The Gagnon holds its own. The several stopes are looking well, and large quantities of ore are daily extracted. Some very rich ore is being taken out of the Clear Grit. The general appearance of this property is very encouraging. Jim Cassidy, who lives below the St. Lawrence mine, while digging a cellar back of his house a few days ago, struck a ledge of ore. Jim has located his find, and is now working the ledge. The recent strike in the Rising Star is opening out well. The work of putting up the new building and other necessary work for the new engines at the Lexington mine is going along nicely. The mine is looking very favorable. The mills are running in the usual satisfactory manner, and there is no decrease in the bullion shipments.

NEW MEXICO.

WATER CANYON DISTRICT.—Socorro Bulletin, Oct. 24: Work on the Jane Bowman will be resumed soon. Will Smythe is shooting mineral out of the Fraells lode. Assessment work on the Nameless mine was completed last week. Work was inaugurated in the Jumper mine this week, and a road is being constructed from the mine to the concentrator. J. J. A. Dobbin, M. McLeish and P. Liddy have compromised their difficulties over the Bonaparte mine, which has been a bone of contention for more than a year past, and the title remains in the possession of the two latter. A Radcliff is deepening the shaft in the Ninevah copper mine. The property looks well.

COONEY CAMP.—Cooney Camp of the U. M. of N. M. is steadily increasing in importance. Sheridan's mine is working night and day, and ore is dumped daily in anticipation of a market. The Miller mill is running uninterruptedly on a constant supply of ore, and is shipping steadily via Silver City. Mr. Cooney is grading the site of his new mill. The plant which he has decided to erect without loss of time will be of the capacity of 20 stamps, and will be supplied with all of the recent improvements. This will give a great impetus to the camp, as the mill which he has formerly operated possessed only five stamps.

MISCELLANEOUS.—The Kelly mine is yielding its usual quota of ore to run the Billing works. The Graphic smelter of this city shipped 18 tons of bullion East on Wednesday. The Billing works are running as usual, and will turn out this month their usual amount of bullion. The Merritt mine continues to work night and day shifts, and is shipping mineral daily for the M. M. & N. Co.'s plant in this city. The Graphic M. & S. Co.'s plant is running its two sacks steadily. It is working smoothly, and producing bullion beyond the anticipation of the management. The Graphic is worked by night and day shifts, under the superintendency of Captain Day, and ships daily consignments of mineral to the Graphic smelter of this city.

OREGON.

BULLION.—Bedrock Democrat, Oct. 29: Yester-

day Cabell Bros. brought to town another clean-up from their mine in Granite district. It was 600 ounces of silver, the result of one week's run, and was purchased at the banking house of J. W. Virtue. This mine will produce sufficient ore to keep an extensive mill in operation, and with facilities for successfully working the mine, the output would be \$10,000 per week.

ANOTHER MILL.—We are reliably informed that Neuner will have a 10-stamp mill in the Pine creek district within 30 days. If this mill is properly managed by a practical miner, and not a theoretical crank, there will be some startling developments in a short time. We have not learned who will superintend the enterprise, but hope to see some practical miner in charge.

WOODVILLE.—Cor. Grant's Pass Courier, Oct. 24: The mining interests on Evans creek are assuming considerable importance now. Much prospecting is being done, and from samples of ore shown us by parties interested, we are led to believe some rich discoveries will be the result of further development. Our opinion of this district is, that if one-fourth of the work and capital expended in other localities was put in prospecting this vicinity—we mean both in Josephine county and that part of Jackson county contiguous—capitalists would at once take hold of and develop the discoveries into paying properties. Among the ledges developed may be mentioned as most prominent, the Oliver Boyd, in the vicinity of Woodville, which has a shaft 34 feet, cutting the ledge 20 feet from the surface, showing gold, silver, lead and copper. The vein is 3½ to 7 feet in width. The owners are talking of taking a rest for the purpose of prospecting other ground, with the best of indications. Stephen Beard has discovered a ledge which he deems a good one, from the fact that development thus far shows that the ore carries galena and sulphates. The ledge is cut by Evans creek, fifteen miles above Woodville, and the owner has the best of encouragement in its further development. John Robinson has a very promising prospect five miles above Woodville, on the south side of Evans creek, which indicates richness both in gold and silver. The formation is granite, and the vein is four feet in width. Messrs. Kinney & Lind have four men working on two quartz ledges near Woodville, with favorable prospects. It is only a question of time and further work when they expect to realize a very handsome return for their expenditure of labor and money. Mr. W. Hale is working a good claim on Grave creek, some distance above Leland, Josephine county. This is a placer, and Mr. Hale informs us that he has taken out and saved \$375 with one sluice box. This shows the richness of the diggings, from the fact that he has only worked them but a very short time. Mr. John Blacklock, on upper Grave creek, is working what he claims to be a good deposit carrying silver and copper. He is also one of the first miners of this section, and will do much towards developing this industry in that part of the country.

QUARTZ ON EVANS CREEK.—Several thousand dollars have been expended in the Evans creek mining district, prospecting quartz, during the summer and fall with very favorable results. Every ledge prospected has continued to improve, and if the ore will work to within three-fourths of assays, there are a number of paying ledges in this locality, though there is more or less base mineral in nearly all of them. Among the most promising ledges are the following: The Blacklock ledge on upper Grave creek, twenty miles from Woodville; the Cooper & Garmann ledge on Evans creek, twenty miles from Woodville; Five miles below is Burs & McKane lode and one mile below is another owned by Neathammer and others, Robinson & Rush have brought in some good-looking ore from a ledge some three miles up Evans creek, where there are five other claims within one and one-half miles from the railroad depot. The most of those who have claims have more muscle than money, and they have been at work with energy and determination, and we have no doubt but what some of them, as they well deserve, will meet with success. Nearly all of the ledges mentioned have this year's assessment work done, and some of the boys will try their luck in placers during the winter, and resume work on quartz again in the spring.

UTAH.

PARK NOTES.—Park Record, Oct. 24: Assessment work is being done all over the hills. The Ontario finally paid off for last month on Tuesday and Wednesday. The lessees of the Bonanza expect to make another shipment in a few days. The Daly Company has a force of men at work fixing the roads in good shape up Empire canyon. The owners of the Roaring Lion have four men at work on the property developing. Work on the Black Diamond was suspended a few weeks ago, but will be commenced again immediately. A first-class ore house is being built at the foot of the dump of the Ontario hoisting works No. 3, which will be a great convenience to the ore haulers. The Daly Company have an immense dump of ore alongside of their ore houses that is being held in reserve for shipment to the mill as soon as it is completed. Work on the Sampson drain tunnel which has been suspended for some time past has been resumed and it is expected that the tunnel will now be pushed until it cuts the ledge and drains the water from the mine. If the company succeeds in accomplishing this result the output of the mine will be materially increased as they will then be able to work to a depth of 500 feet without being bothered with water. Work on the Marsae mill is now confined chiefly to the inside, as the building is now completed and the large force of painters are fast completing the job of covering it with two coats of brown mineral paint. The Anchor works are second to none in the camp. The buildings constituting the hoisting works are not entirely finished as yet, but the foreman, Mr. Martin, calculated that by the first of November all the buildings will have been completed, the machinery put in working order and sinking in the shaft resumed and pushed with all possible speed. Their winter supply of provisions is about all in. There is enough cord wood and timbers on the ground to run them for six or eight months, and by the first of the coming month they will be fully prepared for a long winter of uninterrupted development of this valuable property. The hoisting works are especially calculated to resist the heavy pressure of snow that accumulates in that region during the winter, and no anxiety about that score is felt.

MECHANICS' INSTITUTE INDUSTRIAL EXHIBITION

Of the City and County of San Francisco.

PREMIUMS AWARDED.

SAN FRANCISCO TOOL COMPANY

WERE AWARDED AT MECHANICS' FAIR, 1885.

GRAND SILVER MEDAL.....	BEST DISPLAY OF TOOLS.

Patent Agency.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old
experienced, first-class Agency. We have able and trustworthy Associates and Agents in Wash-
ington and the capital cities of the principal nations of the world. In connection with our edi-
torial, scientific and Patent Law Library, and record of original cases in our office, we have
other advantages far beyond those which can be offered home inventors by other agencies. The
information accumulated through long and careful practice before the Office, and the frequent
examination of Patents already granted, for the purpose of determining the patentability of
inventions brought before us, enables us often to give advice which will save inventors the
expense of applying for Patents upon inventions which are not new. Circulars of advice sent
free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY.

W. B. EWER.

GEO. H. STRONG.

The Debris Question.

The Sacramento Bee has received from Hon. Zach Montgomery the following letter, which is in reply to certain questions touching the debris from hydraulic mining:

DEPARTMENT OF THE INTERIOR, OFFICE OF THE ASSISTANT ATTORNEY-GENERAL, WASHINGTON, D. C., October 18, 1885.

Sir:—I have thus long delayed answering your favor of September ult., touching the debris question, for the reason that I was awaiting the return of the honorable Attorney-General from his much-needed vacation, in order to confer with him on the subject.

He has now returned, and, after a brief interview with him, touching the matters presented in your letter, I am fully confirmed in my previous convictions that, whenever the debris question comes before him in a legal and proper shape, he will not shrink from such action as may be found necessary and proper on his part in order to protect the rights of the Government against the evil to which you refer. Inasmuch, however, as the people of California are themselves the parties most immediately interested in the action they seem to desire at the hands of the Government, it will behoove them to take the initiative by presenting to the War Department a specific statement of the grievances of which they complain, and over which the Federal Government may properly exercise jurisdiction. The matter could then in due course be referred to the Attorney-General for investigation, and, if necessary, for legal action.

Of course there may be many evils resulting from hydraulic mining, affecting the health and property of individuals and communities, which of themselves can only furnish ground for relief at the hands of a State court. But, whenever it is shown to the satisfaction of the proper Federal authorities that the navigable waters of the Government are being seriously obstructed; that her harbors are in the process of destruction; or that the utility of her arsenals or navy yards is being imperiled, it will evidently become the plain duty of those charged with the administration of the general government, as the custodians of the public property and the guardians of the public welfare, to interpose their authority for the prevention of such evils.

As to the real merits of this question, no opinion is here expressed, for the reason that it is not my purpose to prejudge the case. Yet in view of the fact that the courts, both State and Federal, seem to have uniformly adjudged hydraulic mining to be a serious nuisance to those whose property has been made a receptacle for the vast deposits of mining debris, resulting from this peculiar industry, I do not deem it out of place, both as a friend to the miners themselves, and as an advocate of the peace and good order of society, to counsel a strict obedience to the law, as the only course to be thought of for the settlement of this troublesome question. He who pursues a contrary course not only makes himself a public enemy, but blindly rushes to his own ruin. For every one must see that the whole power both of the State and Federal Government must, and will, if necessary, be invoked to enforce the decrees of the courts.

Trusting that the day is not distant when a just, legal—and as far as possible—satisfactory solution of the "debris question" shall be effected, I am as ever the friend and well-wisher of all my countrymen. Respectfully, ZACH. MONTGOMERY.

New Concentrating Plant.

The Tabor Investment Co., of Denver, Col., realizing that mining men in supplying themselves with machinery are guided not only by theoretical calculations, but by facts practically illustrated, have fitted up the old Kimble mill at Twenty-eighth and Blake streets, Denver, with a complete concentrating plant of machinery, the patents of which they control. Their Harris pulverizer contains ten sets of rolls with capacity to pulverize 50 tons per day to 80-mesh. They have also one of the Matchless concentrating tables, called the "New Wonder," on account of its capacity to reach 50 tons per day. They now say to those having concentrating ore, "Bring in a sample as large as you choose to make it and we'll show you exactly what we can do for you."

Last week three runs were made: Boulder county tellurium ore, crude, \$17 per ton; concentrates, \$720 per ton; tailings showing only a trace of gold and silver, running two tons per hour; also \$22-ore from the "Old Lout" mine, San Juan county: Concentrates, \$90; tailings, only trace.

A run on the Col. Sellers ore, at Leadville, made the following showing: Crude ore, 15

EXPLANATION.—Cl, for clear; Cy, cloudy; Fr, fair; Fy, foggy; — indicates too small to measure. Temperature wind and weather at 12:00 m. (Pacific Standard time), with amount of rainfall in the preceding 24 hours.

per cent lead, 30 per cent zinc, \$17 silver; concentrates, 65 per cent lead, 6 per cent zinc, \$90 silver.

As concentrating ore is necessarily low grade and its value principally in its bulk, a machine that will successfully treat large quantities is what mining men have been looking forward to, and the correspondent who sends us the above facts thinks that the "Matchless" plant appears to fill the bill in each particular.

Mining Share Market.

The opening up of the 3100 level of the Hale & Norcross and Chollar through the crosscuts west into the ore vein is making good progress, and is the principal leading feature of the Comstock mining situation at present. Here in the city the stock market is languishing, and will continue to do so until some bona fide development is made in the Comstock mines. None of the crosscuts have yet been advanced far enough west to get into the real merits of the ore vein, except No. 3 in Hale and Norcross, 40 feet south of the deep winze. This cut into the eastern border of the vein, and after passing through two or three small streaks of good ore it was stopped with its face all in good excellent ore, the extent of which can only be obtained by further advancement. Work at this point was temporarily suspended in order to facilitate operations elsewhere, but will be resumed next week. The big hydraulic pump at the Combination shaft being fully completed, all work is now concentrated upon the development of the ore resources of the 3100 level, which will be prosecuted with all due diligence henceforward. Sinking for the 3200 level is not talked of at present, but will eventually be done.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department No. 1, San Francisco.

AUTOMATIC PUMP CO.—Oct. 25th. Capital stock, \$100,000. Directors: W. A. Scollay, E. E. Walker, J. W. Spencer, Porter E. Sanborn, John and E. Lange.

SAN FRANCISCO CHAPTER OF THE AMERICAN INSTITUTE OF ARCHITECTS. Oct. 25th. Directors: George H. Sanders, J. J. Clark, Augustus Laver, J. B. Whittemore and T. J. Welsh.

EQUITABLE BUILDING AND LOAN ASSOCIATION. October 25th. Capital stock, \$1,000,000. Directors: H. Liebes, W. B. Bradbury, J. D. Barr, A. J. Marcus, B. Feigenbaum, Frederick Hess, Charles Alpers and Jacob Goldberg.

RITCHIE CREEK WATER CO.—Oct. 25th. Object: Supplying the towns of Calistoga and St. Helena and intermediate places in Napa county with water. Capital stock, \$25,000. Directors: L. A. Garrett, H. Cramer, M. F. Hitchcock, E. W. Coit and H. N. Clement.

MANY houses are being torn down and removed from Bodie to Hawthorne, Nev., where there is quite a mining excitement.

THE placer mines of Montana, it is estimated, have yielded a total sum of \$150,000,000.

Market Reports.

Lumber at Wholesale.

The Redwood Lumber Association has established no prices since the first of the year.
Rough—Cargos. Prices are at present as follows: Rough, merchantable, 3/4 M ft., \$13.00; Rough, clear and surfaced, \$24.00; 1x10 Rustic, No. 1, \$24.00; 1x10 Rustic, No. 2, \$19.00; 1x8 V Rustic, No. 1, \$22.00; 1x8, tongued and grooved, \$21.00; 1x4, tongued and grooved, headed, \$23.00; 1/2-in. x 3, Batens (board measure), \$30.00; Shingles, 3/4 M, \$1.65.

Pine—Rough, \$15.00; No. 2, \$12.00; do do in lengths, \$13.00; rough, 40 to 50 ft lengths, \$16.00; do 50 to 80 ft, \$17.00; T and C Flooring, 1x6, \$26.00; do do 1x6, \$28.00; do do 1x4, \$23.00; do do No. 2, \$21.00; Vertical Grain T and C Flooring, 1x6, \$30.00; do do do 1x6, \$32.00; Stepping, \$37.50; Furring, 1x2, per lineal ft., 1/4 c.

Lumber at Retail.

Prices fixed by the association April 1st. are as follows:
Pine, Rough, 40 to 50 ft lengths, \$16.00; do 50 to 80 ft, \$17.00; T and C Flooring, 1 x 6, 1 x 8, 1 x 10, 1 x 12, 1 x 14, 1 x 16, 1 x 18, 1 x 20, 1 x 22, 1 x 24, 1 x 26, 1 x 28, 1 x 30, 1 x 32, 1 x 34, 1 x 36, 1 x 38, 1 x 40, 1 x 42, 1 x 44, 1 x 46, 1 x 48, 1 x 50, 1 x 52, 1 x 54, 1 x 56, 1 x 58, 1 x 60, 1 x 62, 1 x 64, 1 x 66, 1 x 68, 1 x 70, 1 x 72, 1 x 74, 1 x 76, 1 x 78, 1 x 80, 1 x 82, 1 x 84, 1 x 86, 1 x 88, 1 x 90, 1 x 92, 1 x 94, 1 x 96, 1 x 98, 1 x 100, 1 x 102, 1 x 104, 1 x 106, 1 x 108, 1 x 110, 1 x 112, 1 x 114, 1 x 116, 1 x 118, 1 x 120, 1 x 122, 1 x 124, 1 x 126, 1 x 128, 1 x 130, 1 x 132, 1 x 134, 1 x 136, 1 x 138, 1 x 140, 1 x 142, 1 x 144, 1 x 146, 1 x 148, 1 x 150, 1 x 152, 1 x 154, 1 x 156, 1 x 158, 1 x 160, 1 x 162, 1 x 164, 1 x 166, 1 x 168, 1 x 170, 1 x 172, 1 x 174, 1 x 176, 1 x 178, 1 x 180, 1 x 182, 1 x 184, 1 x 186, 1 x 188, 1 x 190, 1 x 192, 1 x 194, 1 x 196, 1 x 198, 1 x 200, 1 x 202, 1 x 204, 1 x 206, 1 x 208, 1 x 210, 1 x 212, 1 x 214, 1 x 216, 1 x 218, 1 x 220, 1 x 222, 1 x 224, 1 x 226, 1 x 228, 1 x 230, 1 x 232, 1 x 234, 1 x 236, 1 x 238, 1 x 240, 1 x 242, 1 x 244, 1 x 246, 1 x 248, 1 x 250, 1 x 252, 1 x 254, 1 x 256, 1 x 258, 1 x 260, 1 x 262, 1 x 264, 1 x 266, 1 x 268, 1 x 270, 1 x 272, 1 x 274, 1 x 276, 1 x 278, 1 x 280, 1 x 282, 1 x 284, 1 x 286, 1 x 288, 1 x 290, 1 x 292, 1 x 294, 1 x 296, 1 x 298, 1 x 300, 1 x 302, 1 x 304, 1 x 306, 1 x 308, 1 x 310, 1 x 312, 1 x 314, 1 x 316, 1 x 318, 1 x 320, 1 x 322, 1 x 324, 1 x 326, 1 x 328, 1 x 330, 1 x 332, 1 x 334, 1 x 336, 1 x 338, 1 x 340, 1 x 342, 1 x 344, 1 x 346, 1 x 348, 1 x 350, 1 x 352, 1 x 354, 1 x 356, 1 x 358, 1 x 360, 1 x 362, 1 x 364, 1 x 366, 1 x 368, 1 x 370, 1 x 372, 1 x 374, 1 x 376, 1 x 378, 1 x 380, 1 x 382, 1 x 384, 1 x 386, 1 x 388, 1 x 390, 1 x 392, 1 x 394, 1 x 396, 1 x 398, 1 x 400, 1 x 402, 1 x 404, 1 x 406, 1 x 408, 1 x 410, 1 x 412, 1 x 414, 1 x 416, 1 x 418, 1 x 420, 1 x 422, 1 x 424, 1 x 426, 1 x 428, 1 x 430, 1 x 432, 1 x 434, 1 x 436, 1 x 438, 1 x 440, 1 x 442, 1 x 444, 1 x 446, 1 x 448, 1 x 450, 1 x 452, 1 x 454, 1 x 456, 1 x 458, 1 x 460, 1 x 462, 1 x 464, 1 x 466, 1 x 468, 1 x 470, 1 x 472, 1 x 474, 1 x 4

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT ABSTRACT, 252 Market St., S. F.

FOR WEEK ENDING OCTOBER 20, 1885.

328,560.—GATE.—Jas. Bardin, Jr., Salinas, Cal.
328,762.—BEDSTEAD FOR WIRE MATTRESSES.—T. S. Clark, S. F.
328,663.—WASHING MACHINE.—M. N. Easley, Drain, Or.
329,580.—TOP PLATE FOR STOVES, ETC.—John Forbes, S. F.
328,809.—HOT AIR STOVE.—R. A. Rew, Pomeroy, W. T.
328,521.—SINGLE ACTING ENGINE.—John Richards, S. F.
328,522.—SINGLE ACTING ENGINE.—John Richards, S. F.
328,530.—DERRIER FORKS.—C. Stone, Walnut Creek, Cal.
328,531.—STEAM GENERATOR.—H. Stutsman, East Portland, Or.
328,547.—CAR COUPLING.—A. W. Van Dorston, Portland, Or.
12,609.—TRADE MARK.—W. T. Coleman & Co., S. F.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

SAW.—Henry W. Wheeler, S. F. Assignor to Tatum & Bowen. No. 328,164. Dated Oct. 13, 1885. This is an improvement in inserted-tooth and chisel-bit saws. It consists of supplemental plates or extensions fitted in the periphery of the saw-plate extending outward therefrom, and having their front and rear edges formed to receive the holding-shanks and cutting-teeth or bits. In all inserted tooth and chisel-bit saws the saw-plate wears thin upon the rim or periphery behind the hits from the constant passage of the sawdust and from the friction, and the sockets in which the shanks are fitted soon become enlarged, so that the shanks and bits wear loose from constant changing, and the saws soon become worthless on this account. By the supplemental plates provided by this invention as many teeth may go in the saw as may be got into a solid rim, and the arrangement is such that it will not affect the tension of the saw detrimentally. The invention is applicable to all saws in which the chisel-tooth is used, whether the tooth be held by a shank-wedge or other device, and is applicable to repairing old saws.

GATE.—James Bardin, Jr., Salinas. No. 328,560. Dated Oct. 20, 1885. This is one of the automatic gates which are operated by the action of the wheels of a passing vehicle running down a crank-lever in the roadbed; and the invention consists of a gate centrally pivoted and adapted in the course of its several movements to make a complete revolution, opening and closing the road at alternate quarter-circle movements, a loose sheave on the pivotal axis of the gate and connected therewith by a pawl and ratchet, weights suspended by cords from the sheave and adapted to operate the gate, crank-levers in the roadbed connected by cords with the sheave, whereby said sheave is rotated to wind up the weights, in sliding latches limiting the gate and connected by pivoted levers and cords with the crank-levers and sheave, whereby they are withdrawn by the action of the vehicle wheels on the crank-levers.

PIPE-WRENCH.—Richard E. Williams, Modesto. No. 328,167. Dated Oct. 13, 1885. This relates to that class of pipe wrenches in which a curved corrugated jaw is pivoted to a stock or handle and works in connection with a fixed corrugated jaw on the end of the stock or handle. The invention consists in the novel arrangement of the two jaws, and in an improvement by which they are guided and held in a true position when in operation. Both jaws are of the same thickness, and lie flush with each other, so that the wrench will have a good grip on a short pipe.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical and scientific progress, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.
J. J. BARTELL—Amador and Calaveras Co's.
F. H. HORN—Nevada (State).
G. W. INGALLS—Arizona.
E. L. RICHARDS—San Bernardino Co.
R. G. HUSTON—Idaho and Montana.
Geo. McDOWELL—Fulmer and Fresno Co's.
HUGH ELIAS—Nevada Co.
J. DE PUE, Sutter and Butte Co's.
B. E. LLOYD, Stanislaus and Merced Co's.
J. WINKLER, Alameda Co.
T. BATES, Shasta and Tehama Co's.
M. L. DENNIS, Plumas and Sierra Co's.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

NEW BOOKS ON ASSAYING.

By C. H. AARON.

PART I.—Gold and Silver Ores.—Price \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes thereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications "Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores," that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Methods; The Assay Office; Preparation of the Ore; Weighing the Ore; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expellents; Assay Tables.

The volume embraces 166 12mo. pages, with illustrations, well bound in cloth. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

PARTS II AND III.

Lead, Copper, Tin, Mercury, etc.
Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Assay of Silver; Manipulation, etc.; Lead Ores; Copper Ores; Volumetric Assays; Parkes' Process; Amalgamation; New Process; Preparation of Potassium Zanthate; Electrolytic Determination of Copper in Ores, etc.; Assaying of Tin Ores; Assaying of Mercury Ores; Assaying of Zinc Ores; Assaying of Zinc Ores, New Method; New Assay of Nickel and Cobalt; Assay of Chromium; Assay of Bismuth; Assay of Arsenic; Assay of Antimony; Assay of Sulphur; Assay of Selenium; Appendix to Part I; New Assays; Weighing by Oscillation; Appendix to Part III; The Assay of Lead; The Assay of Copper.

There are 160 12mo. pages with illustrations in the volume, which is bound strongly in cloth. Price postpaid, \$1.75. Sold by DEWEY & CO., Publishers, No. 252 Market St., S. F.

These are much needed books for miners and other practical men, by an intelligent miner and assayer and careful writer. They are invaluable for the mill and mine worker, and equally good for scientific experts. They are thoroughly practical books.

THE ROLLER ORE FEEDER

(Patented May 28, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

Golden State and Miners' Iron Works.
Sole Manufacturers,
237 First Street, SAN FRANCISCO, CAL.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

ASSESSMENT NOTICE.

Orleans Mining Company.—Location of principal place of business, San Francisco, California. Location of works, Grass Valley, Nevada county, Cal. NOTICE is hereby given, that at a meeting of the Directors, held on the 17th day of September, 1885, an Assessment (No. 12) of Five (5) Dollars per share was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary at the office of the Company, 934 and 936 Mission street, San Francisco, Cal. Any stock upon which this Assessment shall remain unpaid on the second day of November, 1885, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on Monday the twenty-third day of November, 1885, to pay the delinquent Assessment, together with costs of advertising and expenses of sale.

GEO. P. THURSTON, Secretary.

OFFICE—934 and 936 Mission St., San Francisco, Cal.

THE ORIGINAL Roller Ore Feeder.

(PATENTED JUNE 24, 1873.)

This form of Ore Feeder is well adapted for its peculiar work. Manufacturers of the Celebrated "Challenge" Ore Feeders for any character of ores; also "Stanford Improved" Ore Feeders and Tullock's Ore Feeders for dry ores.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont St., San Francisco.

F. A. HUNTINGTON'S CENTRIFUGAL ROLLER QUARTZ MILL.

Economy in Expense of Plant. Economy in Cost of Working. Economy in Saving Gold. Economy in Transportation of Machinery. Economy in Cost of Erection of Mill at Mine. Economy in Time Required to Establish Plant (one day only being consumed).

The Huntington Mill has passed entirely through the experimental stage. Two years of continuous use at a number of mines in California has enabled the inventor to perfect and improve the machinery until he feels justified in assuring the public that he has reached THE ABSOLUTE in the construction of a perfect Quartz Mill.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et al.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

IMPROVED HYDRAULIC MACHINE.

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

HOSKIN & CO., Marysville, Cal.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over other Valves and Gate Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
 2. Sand or grit of any kind will not injure the seat.
 3. You do not have to take them off to repair them.
 4. They can be repaired by any mechanic in a few minutes.
 5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.
- In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Disc." For sale by

\$1,000 CHALLENGE!

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS,
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove this Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1863, Dec. 22, 1874, Sept. 2, 1870, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all the AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED 1860.

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enabled us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not few. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

Number 19.

Reading for Mining Camps.

Several miners employed in a mine in Idaho agreed recently to club together and subscribe for a number of papers for winter reading. The idea is a good one and should be followed by miners in other places. Even in those mining camps where mining is carried on all winter there are many days when little can be done, and the long evenings are apt to be tedious in any case. Loafing around saloons and playing cards is, to say the least, an unprofitable amusement, and one which is apt to pall upon the taste of the more intelligent people. There are some, of course, who will never read under any circumstances. They can, but they will not. They are perfectly satisfied with their experience and do not care to learn that of others. As a consequence they often commit blunders or make mistakes which might have been avoided had they read of the experience of others. Reading men are, of course, apt to be better informed and more intelligent than those who never look at a newspaper or technical journal devoted to their special branch of business.

It is found, however, that even those with no special taste for reading will take books occasionally to examine if they have the opportunity. In most mining camps there are no libraries and little reading matter; but when books are to be had they are eagerly read by some of the men. The writer of these paragraphs well remembers his experience in that matter some 15 years ago in a little mining camp in this State. Among other things brought to his cabin when he found it was probable he would stay a year or more, were a couple of hundred books. Some were on mining and metallurgical subjects, but most of them were standard works of English literature. The books in that little library were read and re-read by many miners in the camp, a large proportion of which had never had an opportunity to peruse works of the class. Many were the thanks received by the writer for pleasant hours given by means of these books. He also had the city dailies, the magazines, and the illustrated weeklies sent to him regularly by a kind and remembering mother. When the mail came once a week there were always several dozen miners from the neighboring cabins who came to see these papers, and they went from hand to hand until the next batch came. It was surprising to see how eagerly they were read.

The means employed by these Idaho miners—that of clubbing together—gives them the advantage of having a number of papers for small expense. Not only the local papers, but the great city dailies, the magazines, technical and mining papers may be subscribed for. Their presence in saloons or boarding houses is sure to exercise a good influence. They result in discussions and interchange of views, and serve to while away many hours which might otherwise be passed in idleness. It is not idleness to read, by any means, for men improve themselves thereby, which they do not do unless occupied in some way. The example of the miners referred to can be followed in many a camp to the great benefit of those who take advantage of it.

Four tunnels are to be run into Red Mountain, Montana, for mining purposes. It is supposed there are many quartz veins in the mountain.

The Tustin Ore Mill.

The Tustin ore mill is intended to obviate the necessity of using stamps in pulverizing ore. It was invented several years since, and has been improved from time to time as experience dictated, until now it is considered a perfect piece of mechanism for the purposes for which it is intended. Messrs. Hinckley, Spiers and Hayes of the Fulton Iron Works are the agents and manufacturers for this coast, which is sufficient guarantee of the character of the construction of the machine.

The mill is capable of working ores either wet or dry, and feeds itself automatically. We

For this machine the inventor and manufacturer claim the following, among other special points of merit: cheapness, lightness of weight, being comparatively small; compactness, requiring but little room; requires but little power to run it, $3\frac{1}{2}$ horse-power being sufficient; is easily set up, two men being able to put it up in two days, and no expensive foundation being required; it runs so slow that it does not heat, makes no noise, and creates no dust; it feeds itself automatically; granulates the ore uniformly, and makes but little slime, which so interferes with successful amalgamation, leaching or concentrating; the wearing parts are durable, consisting of hard cast-iron, which can be readily

THE IMPROVED TUSTIN ORE MILL.

present here a cut of this mill with a portion broken away to show the interior arrangement. The cylinder in this (the largest sized machine) is 54 inches in diameter, 18 inches between heads. Slotted dies secure the circumference of the heads in place, and wire screens are secured outside of all. Inside the cylinder, and resting loosely on the dies, are two cast-iron rolls, weighing respectively 700 and 1000 pounds.

The cylinder revolves on journals, and is driven by gear which turns it 25 times a minute.

The ore is fed from a hanging hopper through one of the journals, which is hollow. In action the rolls revolve in the opposite direction from that in which the cylinder turns. The ore being fed in, is crushed between the rolls and the dies, and drops through the slots in the screens, where what is fine enough is sifted through, and what is too coarse is again carried under the rolls. Horse-power required $3\frac{1}{2}$; capacity, 30 tons roasted ore per 24 hours, or from 12 to 20 tons raw ore, depending on its hardness.

removed and new parts put in, and is so simple in all its parts and construction that but little skill is required for setting it up, or repairing or running it.

This inventor and manufacturers of the Tustin machine have numerous letters from millmen and metallurgists testifying to its good points as above set forth. It has also on several occasions been awarded a premium by the Mechanics' Institute, as the best quartz mill exhibited, whether for wet or dry crushing.

One of these machines can be seen at the Ore Sampling and Pulverizing Works of Messrs. Hofmann Brothers, S. W. corner Fifth and Bryant streets, San Francisco, where it is in daily operation. It is the smallest size, capacity equal to a five-stamp battery, and will pulverize from five to ten tons in 24 hours, according to the hardness of the ore, through a No. 40 mesh screen, $1\frac{1}{2}$ horse-power required. Weight, 5000 pounds; heaviest piece, 425 pounds. Price, \$600. Larger size, weight, 11,000 pounds; heaviest piece, 1100 pounds; price, \$1100; capacity, 12 to 20 tons per day; $3\frac{1}{2}$ horse-power required.

Distribution of Ores.

The regularity of the distribution of ores in the Pacific Division of the United States and its relation to the irregularly uniform topography, long ago drew the attention of writers to the resources of this region. Mr. W. P. Blake first published a note on the subject in 1866, and his statement was accepted and enlarged upon by Clarence King in 1870. The more detailed technical and scientific investigations of later years have greatly increased our knowledge of the distribution and extent of the ores, and it will now scarcely be maintained there are more than four well-defined and continuous ore belts west of the Rocky mountains. Dr. Geo. F. Becker, in his "Geological Sketch of the Pacific Division," in referring to these belts, says: Beginning at the east the first is that at the western part of the Wahsatch and the southwestern continuation of that range. With the exception of the Leeds (Silver Reef) district all the important ore deposits of Utah lie in the foothills of this range, bearing a very definite relation to the main line of crests.

The gold and copper belt of California stands for a long distance in a similar relation to the Sierra Nevada. The quicksilver belt on the California coast ranges is not quite so regular in its occurrence, yet its direction is nearly parallel to the coast, and it is very persistent, though nowhere broad, for some 300 or 400 miles. The Arizona belt is less known than any of the others, but no one can glance at a map of the Territory showing the mining districts without perceiving that these lie in a northwestern and southeastern line diagonally across the country. The mining districts in Nevada are extremely numerous, so much so, indeed, that some grounds could be given for assuming a belt to run in almost any desired direction, but they are scarcely close or regular enough to any one line to compel the observer to regard them as connected.

Agents and Correspondents.

We have a number of agents and correspondents now at work in different places on this coast, who are gathering information for the benefit of our readers and taking subscriptions at the same time. Mr. J. J. Bartell is engaged in Amador and Calaveras counties; E. L. Richards, San Bernardino; Geo. McDowell, Tulare and Fresno; Hugh Elias, Nevada county; J. De Pue, Sutter and Butte; B. E. Lloyd, Stanislaus and Merced; J. Winkler, Alameda; T. Bates, Shasta and Tehama; M. L. Dennys, Plumas and Sierra. In the State of Nevada, F. H. Horn is traveling for us; in Arizona, G. W. Ingalls, and in Idaho and Montana, R. G. Huston. The first of the series of letters from Mr. Huston appears in this week's PRESS.

As we send none but worthy men to represent the PRESS, we hope that our friends and subscribers will extend to them such courtesies as may lie in their power. It is often easy to greatly aid our agents and correspondents in the various towns and camps by assisting them in gaining information and indicating those persons likely to be regular readers of a paper like the PRESS. We aim to make a paper which will be of value to the industrial classes of this coast, but need their co-operation to carry on the work satisfactorily. Those who will assist our representatives at the points they visit will place us and them under great obligations.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Notes from the Interior.

The Changes of 36 years—Mining and Milling Quartz in California—Where the Miners Can Still Make Wages.

EDITORS PRESS:—Visiting not long since the central mining counties of California, portions of El Dorado and Placer included, I had occasion to cross the deep canyon through which flows the Middle Fork of the American river, making the passage at what is now known as Grey Eagle "Bar." The last time I had made this crossing was just 36 years before, but I found the trail coming up on the south side just as steep, and not much different otherwise now from what it was then. There was the same sixteen hundred feet to be climbed in advancing a direct distance of a little more than one mile, and the same zig-zag trail, increasing the distance, as traveled, to nearly three. There have been constructed fine broad wagon-roads across these canyons, but they are generally a long way apart, with only foot or bridle trails for crossing along the intervals between them. But you will say I found the general aspect of the country greatly changed from what it was 36 years ago. No, I did not. In its general aspect it has changed very little. The scattered forests of cedar, spruce and pine cover the tall red hills as before. The deep, dark canyons remain the same. Here and there you come to a miner's or a woodman's cabin, or a settler's house and barn, with some land enclosed, some fruit trees planted, and perhaps a little grain raised. At longer intervals you strike a quartz mill or a mining hamlet, the larger towns being few and far between. Away from the railroad there is not in Placer county a town containing a thousand inhabitants, nor in El Dorado more than two or three that have a greater population than that.

And yet the mining industry throughout this region, hydraulics excepted, is in a generally healthy and prosperous condition, much solid progress having been made during the past two or three years. With the subsidence of stock gambling and other mere speculative movements the business began to improve, mine owners going to work on their claims and getting them into proper shape for producing bullion instead of doctoring them for a stock deal, or holding them for a market. Since applying themselves more earnestly and honestly to the business, our miners have learned it pretty well, and are now turning this knowledge and the experiences so acquired to good practical account.

The advances made in quartz mining are very noticeable, especially in the matter of introducing labor-saving machinery, as the incident I am about to relate tends to establish. Coming up the trail aforesaid about the first of the present month, I heard, when near the top, the pounding of a quartz-mill, which a little further on came in sight. Arrived at the place, I entered without knocking, there being enough of that going on within. These quartz mills are, in fact, rather open institutions, especially about the base, where on this occasion I made my ingress. Here is where the settlers are located, and I was not surprised to find them doing their work without an attendant, as indeed none is necessary. On the next floor above, the amalgamators were in like manner grinding away with no one in sight: ascending still higher, where the concentrators were looking after the sulphurets, I naturally expected to find someone around, but I did not, nor did I see a single person in or about that quartz mill going from bottom to top, and for the very good reason that there was no one there: not a man, even in the battery room, as, why should there be, seeing the cams were lifting and dropping the stamps with due regularity without any human assistance, and the self-feeders were supplying the ore to the batteries more evenly and steadily than could be done by hand? So, too, the grizzlie and the rock-crusher, located higher up, being able to get along for a time without looking after, why should not this day attendant have gone out into the cooler air and seating himself on the log, where I found him, proceeded to discuss the political situation with lawyer nongues? The well-appointed quartz mill may very properly be left to take care of itself, but how shall the political machine be run without looking after? Of course, this was the sensible view taken of the case by him on the log.

And now lest it be supposed that a mill so left to itself must necessarily do its work in a slovenly and wasteful manner, let me tell you that such is not the case: operations at this mine, the Josephins, being conducted as well and as cheaply, perhaps, as at any other in California, the cost of ore extraction and reduction being only \$1.50 per ton. Not only so, but the owners are planning to reduce this figure. After a time, when ore hoisting shall come to be done by connecting the gear by means of belts and pulleys with the present motive power, raising the ore will not cost over 90 cents per ton instead of \$1, as at present. This change in the machinery effecting the two mill attendants, one by day and the other by night will have to apply a portion of their spare time attending to the hoisting signals. Such is the progress being

made in quartz mining and milling in California. When human agencies shall have been wholly eliminated from the business there will be an end of changing shifts and labor strikes.

Leaving this time, labor, and gold-saving establishment, a further descent of a few hundred feet brought me to the top of the Georgetown Divide, where I found still other works of this kind operating with almost equal economy. One reason that quartz milling can be carried on here at so little expense being the cheap water power supplied to many of the mills by the California Water Company, whose large and well-constructed ditch traverses this divide throughout its entire length. This property, now in splendid condition and carrying a heavy flow of water, is under the management of the Hon. Thomas Findley, who has also charge of the Idaho quartz mine, a valuable and well conducted property, equipped with a five-stamp mill, and situated a few miles above Georgetown.

Coming further down towards Greenwood, we arrive in the country of the seam diggings, small, rich veins of quartz got out with picks and crowbars, aided, sometimes, by hydraulic pining. Only a few miners are at work here, though I see no reason why a great many might not find profitable employment in these diggings, as the veins are rich, numerous and capable of being worked at little expense. Here is a favorable field for the employment of the small hand crusher, invented by a member of the house of John Taylor & Co., who, having completed a number of these machines, are just putting them on the market. I see by advance sheets of the book entitled "Gold Mines and Mining in California," about to issue from the press of Geo. Spaulding & Co., that this district will be designated as one of the places where the working miner can make at least living wages in California, this pointing out of such localities being one of the many valuable features of that book.

HENRY DEGROOT.

Calaveras County Mines.

EDITORS PRESS:—In the halcyon days of '49 when the turbulent miners were digging out the precious metal from the numerous streams, bars and gulches throughout the foothills of the Sierras, this upper terrace of the mountains remained unprospected, and was yet a howling wilderness, where the Digger Indian still roamed amid these lofty pines, undisturbed by the untimely intrusions of civilized man, and the deer still grazed on the thousands hills as he had for a myriad of centuries past. But this state of affairs was not permitted to be prolonged in a region so approximate to a field that was being furrowed by the adventurous miner.

In those early days the miners that worked on the Mokelumne river diligently followed the coarse gold to a certain locality, situated below the intersection of the confluent of that golden stream. From the point where the coarse gold ceased to exist, the fine gold commenced and continued to higher altitudes, and this proved evident to the more experienced: that gold-bearing quartz existed in the higher Sierras; so doubts and theories were not allowed to rest, and were soon brought to practical test. The Mexicans took the initiative step towards prospecting this new region, they having mastered the art of quartz mining in their own primitive methods, in the State of Sonora. They were the only class in those early days that understood quartz and prospecting for it. So a party of Sonorians started at once from Campo Seco and Lancha Plana, in quest of that which might substantiate their visionary dreams. After one day's journeying into the mountains they pitched their tents on the right bank of the north fork of the Mokelumne river near the American bar, and opposite what is now known as the old Bucher's ranch. Their pains were soon rewarded by finding a rich quartz ledge, which yielded many thousand dollars worth of ore, and was afterwards known as the Campanya mine. Mule arastras were used to reduce the ore taken from the mine.

The next party that followed was a squad of Texan rangers. Tom Deer and Pete Gass were among them. Pete is to-day lingering in the Calaveras county hospital, and spinning yarns of his black bean experience of the ill-fated Mer expedition. The valiant Tom Deer afterwards died gone on the remote frontier, and so all those "boys" have passed in their "checks," except Pete. When the rangers arrived at the Mexican Camp, the river was swollen from the melting snows above, but as soon as the raging torrent receded and became passable, they crossed the stream accompanied by Campanya, a Mexican, and discovered the Texas Lone Star and Riverside mines.

All this happened in the summer of 1853. The subsequent influx of miners was large, and cosmopolitan in character, the Mexicans predominating. The town of West Point was soon started, together with minor hamlets, Camp Catarro and Camp Flores, these last two being in the midst of a network of quartz ledges that yielded abundantly. The first store was started by Fernando Dudino, in 1854, and was constructed of pine logs, one Stevens being the architect. A grape vine arbor marks that spot to-day, and it was where West Point was first founded. It was then hidden in the midst of a dense forest of pines. Roads were built to the outer world; a ditch was dug to carry on gulch mining and to supply the many

quartz mills; a saw-mill was erected, and more pretentious building was carried on. More stores, saloons, gambling dens and dance-houses were soon in vogue; the population increased, and the surrounding hills were soon teeming with prospectors. The musical ring of the prospector's hammer could be heard in every direction. Strikes were made almost daily. The arastras kept up their incessant grinding. Gambling and carousal was carried on night and day. The then novel way of mining, so uncommon elsewhere, was here in the glory of its palmy existence. This outfit of the miner in the way of tools, consisted of a pick, shovel, hammer, tub, rope and windlass. The latter was so constructed as to make it quite portable to carry over the hills. The soft nature of the syenite granite facilitated prospecting by sinking round, vertical shafts, three feet in diameter; 10 to 20 feet was considered a day's work, and as much as 30 feet has been sunk in one day when all conditions were favorable. Stamp and arastra mills were being built, which soon supplanted the tedious mule arastras. All ores extracted from the confines of the walls of the decomposed granite were quite oxidized, which greatly facilitated amalgamation; but as greater depth was attained in the mines, where hard ground and water was reached, the sulphurets came in, making the ore very rebellious, and consequently low-grade, by the ordinary mill process. The miners here never bothered their heads about solving problems to work sulphureted ores, as the field was too large and unexplored to harass themselves by sinking in hard ground and water, so they would pack their windlass and tools, and proceed to make a new find in soft granite. The result would be that the abandoned mine would cave in the following winter, the owners would leave the camp, or "kick the bucket," and its record would be erased from memory's storehouse and sunk into oblivion.

Twenty-five quartz mills have been built in this district since its discovery, and to-day only five mills remain in working condition; for as soon as the oxidized ore was all found and worked out and thence became bare, many mills were compelled to shut down, and left to rot. The ore of this district contains more sulphurets and of a greater variety than any other locality in this State, consequently it has been a good field for experimenters, and many scientific men have taken advantage of that condition and visited this place for the purpose, and not meeting with the desired success have left the field open to the next scientist. So the work has gone on for many years, marked by fruitless attempts to accomplish the object aimed at.

And it is only lately that this mystery has been solved, and that is by the Russell process of roasting ores. It has convinced the most incredulous mind as to its efficacy in working successfully rebellious sulphureted ores, including tellurium. The latter mineral was not known to exist here till lately, and it is quite rich when found. In my next letter I will confine myself to the description of the principal mines, or those that are worthy of attention.

FRANK M. OCHOA.

West Point, Calaveras Co., Cal.

Gold and Silver Bullion.

Dr. James P. Kimball, Director of the Mint, has submitted to the Secretary of the Treasury his annual report of the operations of the mints and assay offices of the United States for the fiscal year ending June 30, 1885. This value of gold deposited at the mints and assay offices during the year was \$56,748,752, of which \$3,854,677 consisted of redeposits. Of this gold deposits nearly \$32,000,000 consists of domestic bullion, over \$11,000,000 of foreign bullion, and some \$3,000,000 of foreign coin. The value of silver deposited for bars and purchased for coinage, computed at its coining rate in silver dollars, was \$38,082,222, of which \$1,292,447 was redeposits. Of the silver deposited and purchased, over \$32,000,000 was classified at the mints as of domestic production, \$2,000,000 was of foreign bullion, and \$1,000,000 of foreign coin. The total coining value of gold and silver deposited and purchased at the mints was \$94,830,976, against \$97,955,154 in the previous year. The decline in the production of

Gold on the Pacific Coast

Is shown by a continued falling off of the deposits at the Mint in San Francisco, the value of gold deposited at that institution having declined over \$8,000,000 since 1881. The total imports of gold bullion into the United States was \$5,849,237. The deposit of gold bullion, classed as foreign at the mints, was over \$11,000,000, from which it would appear that over \$2,000,000 worth of gold bullion had reached this country which was not entered at the Customhouses.

The imports of silver bullion amounted to \$11,530,381; imports of gold coin amounted to \$17,842,459, of which \$3,352,090 consisted of American coin and \$14,490,369 of foreign coin. The imports of silver coin were \$12,020,243, of which \$673,926 was American coin.

The imports of gold bullion amounted to only \$395,750, nearly all of which was United States bars. Of silver bullion the very large sum of \$20,422,924 was exported, only \$1,500,000 worth of which consisted of bars bearing the stamp of the United States mints or assay offices. From this it will be seen that about \$19,000,000 worth of the silver production

of this country found its way abroad by export.

The export of American gold coin amounts to \$2,345,809, and of foreign gold coin to \$5,736,333, a total of \$8,082,142. The export of American silver coin amounted to \$1,211,627 (\$1,073,150 of which consisted of trade dollars) and the export of foreign silver coin to \$12,060,612; some \$10,000,000 of the amount being exported at the port of San Francisco.

The Coinage Expected

At the mints during the year was: Gold, \$24,866,112; silver, \$28,848,959; minor coins, \$52,755. Total, \$54,237,639. Of the silver coinage, \$28,528,552 consisted of standard dollars. In addition to the coin executed, gold bars were manufactured of the value of \$32,027,463, and silver bars of the value of \$9,549,313, a total of \$41,576,776. The bars manufactured exceeded by some \$10,000,000 the value of those produced in the previous year. The total value of gold bars exchanged for gold coin was \$2,065,021 against \$25,800,799 the previous year, showing a large falling off in this demand for gold bars for export. The silver purchased for

Standard-Dollar Coinage

During the year was \$24,212,412 standard ounces, costing \$23,747,460. The average price paid for silver during the year was \$108.9 10. The average London price was about \$109.2, and the average New York price was \$109.1. The seignorage of this Government was some 18 per cent on the cost value of the bullion. The seignorage on the coinage of silver dollars during the year amounted to \$4,355,278; of subsidiary silver, \$10,198, a total of \$4,365,476. The seignorage on the coinage of silver from July 1, 1878, to June 30, 1885, amounted to \$25,338,389. The number of silver dollars distributed by the mints during the year was 20,373,625. The number in circulation increased from 39,794,913 on July 1, 1884, to 45,275,710 on Oct. 1, 1885. The number in the Treasury increased during the same period from 135,560,916 to 165,438,721.

The Total Amount Expended

For the mint service during the year was \$1,265,519. The total earnings of all kinds, including seignorages, amounted to \$5,147,210, and the total expenses and losses of all kinds to \$1,585,256. The total loss of the precious metals, arising from the wastage of operative officers and sale of "sweep" aggregated during the year \$34,048, while the total value of surplus bullion recovered was \$66,355, showing an actual surplus in the operations of gold and silver during the year of \$32,307. The Director estimates the amount of gold and silver

Coin in the Country

On July 1, 1885, at \$20,000,000, of which \$542,000,000 consisted of gold and \$278,000,000 of silver. This amount was owned as follows: By the United States Treasury, gold, \$53,223,160; silver, \$95,119,056; total, \$148,342,225. By the National Banks, gold, \$156,575,867; silver, \$11,978,833; total, \$177,554,700; by other banks and private hands, gold, \$323,375,609; silver, \$171,726,303; total, \$495,101,912. The Director has deducted the amount of the coin in the Treasury, represented by gold and silver certificates outstanding and added it to the stock of coin in circulation. In addition to the coin in the country there was in mints and assay offices on July 1, 1885, gold and silver bullion available for coinage as follows: Gold bullion, value, \$66,847,695; silver bullion, which cost \$4,654,587. Total, \$71,501,682. Adding this to the amount of gold and silver coin in the country, it gives the total coin and bullion at that date as \$92,500,518.

The Director calls attention to the necessity for improved facilities for the storage of coin and bullion at the Mints.

The saving effected at the San Francisco Mint since July 1, 1885, by the reduction of the force amounted to an annual decrease of \$35,000.

At the Carson Mint the entire force of workmen and a large portion of the officers have been dispensed with.

A NEW MINERAL.—Messrs. Cross and Hillebrand, of the U. S. Geological Survey, report a new mineral analogous to cryolite, from St. Peter's Dome, in the Pike's Peak region. It occurs in irregular, colorless masses, in pectolite, and possesses the following composition:

Aluminum.....	11.32
Calcium.....	0.72
Magnesium.....	0.22
Potassium.....	28.94
Sodium.....	9.96
Fluorine.....	46.98
	98.08

The name *elpasolite* is proposed for it, from the county El Paso, in which it was found. St. Peter's Dome has been prolific of a number of minerals which heretofore have been found only in Greenland. They comprise cryolite, pectolite, thomsenolite, ralstonite, gearkuite and prosopite, the latter having previously been found only in the tin-bearing veins of Altenberg in Saxony.

The New York Engineering and Mining Journal says that the Cassell process, so emphatically endorsed by Louis Blanding, is neither new nor practical. The Journal concludes its remarks thus: Notwithstanding the prominence given to this new process in the London engineering and mining papers, and the assertions made of wonderful results obtained or obtainable at a cost of from \$1.25 to \$2.50 per ton of ore treated, we are inclined to look upon the statement made as requiring confirmation by higher and disinterested authority.

MECHANICAL PROGRESS.

The Results of Improved Machinery.

Overproduction—Where Will It End?

At the recent meeting of the Institution of Mechanical Engineers, at Lincoln, England, the address of welcome was given by Dr. King, the Bishop. In the course of his address the reverend doctor gave expression to sentiments and thoughts which gave evidence that he had given much thought to the mechanical and manufacturing industries of the day.

In our progress toward the subjection of natural forces to the will of man, it appeared to him that we were tending toward a most extraordinary state of things. The remarks of the speaker under this head have been summarized by the *Textile Manufacturer* substantially as follows:

Before the days of steam power, and when the loom, for example, was wholly driven by manual labor, one individual worker could not possibly attend to more than one machine, for the constant presence of the worker was required in order to keep the machine at work. What has steam power done for the weaver? It has relieved him of his severe labor, and left him with nothing to do but the light work of piecing broken threads, or reeling the shuttle and generally watching the good performance of the work of the machine. But it was very soon found that one man or woman could do more than this, and in place of tending a single machine it became the custom for one worker to superintend two machines; and, as the machine improved in quality and the turning of the steam engine also improved in regularity, another and another loom was added to the charge of each worker, until now it is not uncommon for one worker to superintend perhaps four to seven looms, while at the same time the rate of work of each loom has progressed rapidly; the number of picks, from being perhaps 20 to 40 per minute in the hand loom, having attained from 100 to 300 in the most modern machines of a like width. Thus the number of yards produced has increased, say fifty fold.

Now, so long as a large number of the earth's inhabitants require clothing which they cannot provide for themselves, the above state of affairs may, and will continue, but during the last few years, more especially in England, who have for long had a supremacy in foreign trade, have been confronted with the fact that many of our old customers have begun to manufacture for themselves, and not only this, but they also aim at making for others who still buy from us. As civilization progresses, the disproportion between makers and users will become smaller still, and perhaps finally disappear, and the nearer we approach to the time when each nation shall make for themselves the more tense will become the situation.

Long before such a time comes, however, we shall have some alteration. We cannot go on making millions of yards of cloth which no one will buy, and the weavers will have to turn to other pursuits. Such, however, are not open, for every worker will be confronted with the fact that his productions are not required, and all will be seeking other pursuits and not finding them. It is therefore evident that changes must be made before this state of affairs is reached.

The change required is lessened production. As the world now stands, it would not be practicable for us as a country to say we will at once reduce our productions one-half. It would be the signal for our downfall, for the Germans and the French would at once seize the opportunity to produce a great part of our relinquished half. But the time even then would still surely arrive when they also would have to restrain production; and it is clear that some day all manufacturers will have to do this.

When that time arrives, it will be seen how machinery has reduced toil. So far the employment of machinery appears to have simply tended to the production of more goods. We have used it simply as a means to assist us in doing more work, but not, as we ought to have done, to enable us to do in one day the work of a whole week. We have been content to work along at the old strain with an assistant that has done 98 per cent of the labor, the remaining two per cent alone having devolved upon us; but we have put into the two per cent remnant the whole of the energy which we formerly expended upon the 98 per cent, which the machine now does for us. Thoughtful minds may have long foreseen what must inevitably be the result of this.

A Great Revolution Before Us.

Such a condition of things cannot continue. We must either do away with machinery, or employ it for an hour instead of a day. To dispense with machinery is out of the question and this leaves only the other course open to us. How such a mighty revolution can take place we do not clearly see; we only see that the question is looming up more distinctly day by day and week by week. The distant rumbling of the storm has been heard in various quarters. When the storm has passed, which it will do, though not in our time nor perhaps for centuries, yet it will leave the world better for the change.

It is well that the people should recognize facts which are becoming palpable to many thoughtful men. We live in an era of overproduction. The only way that we have yet been able to find to reduce the surfeit has been

to find a fresh market. This we have found from time to time, and in the present strait all eyes are turned towards Africa as a new and extensive outlet for goods. Open up Africa, say our merchants, and it will absorb all and more than we can produce, and leave enough for our Continental rivals also. Granted, we exclaim, but when Africa has been opened up, what next? Let Australia first be filled with people. So be it; but how when, like the United States they become their own producers? What must next be done? Where shall we turn for a fresh market when the whole earth is civilized throughout? Some nations must, of course, hold pre-eminence in certain pursuits, but the final result to the world at large can be but one—a partial cessation from toil. We shall have to do less and learn more. What we do will have to be done well. What we produce will have to carry the impress of beauty. We shall have to change many things now existing but the change will be for the better. The force of competition will have run its course, for it is not possible that it can last forever.

Brazing Cast-Iron.

A correspondent of the *American Machinist* writes that journal as follows: "What is the reason that I cannot braze cast-iron?" asked a machinist the other day. "Every time I try, I fail. Sometimes the cast-iron burns away, and sometimes the brass will not stick. What is the reason?"

Cast-iron may be easily brazed, if, like doing other peculiar jobs, "you know how to do it." Have the iron clean; make it free from grease and acids, which may be injurious; choose any soft brass, or make some for the purpose. The yellow brass used in brazing copper will do; it must contain a large percentage of zinc, or its melting point will be not much lower than that of the cast-iron itself.

Put on the horax before heating the iron. Dissolve the horax, and apply the solution freely to the parts to be brazed. By doing this before heating, a film of oxide is prevented from forming upon the iron. Fasten the parts together, and heat in a clear charcoal fire. Soft coal is not suitable; there is too much sulphur in it.

Heat the work gradually. Apply the heat to the largest piece, and keep that piece the hottest. Sprinkle on powdered horax and brass filings, and use plenty of horax. Watch carefully, and get the iron up to a red heat before any of the brass melts. The brass will not adhere unless the iron is hot enough to melt the brass.

Be very careful not to get the iron too hot, or away it melts and the job is lost. When the brass "runs," remove from the fire immediately, and wipe off the superfluous brass, cool off slowly, and finish up the joint.

IRON TELEGRAPH POLES.—A metallic telegraph pole has been adopted by the Canadian Government for its telegraph lines on the Northwestern prairies. The pole is constructed of malleable galvanized iron, and is one and one-half inches in diameter at the top, and two and one-fourth inches in diameter at the bottom, and weighs less than 50 pounds. The bottom of the pole is set into a claw plate, upon which the earth is closely packed to a height of about two feet. Then another plate is put into place around the pole, and the earth packed upon it to the level of the ground. The claw plates take a hold in the ground at once, so that the pole becomes solidly fixed immediately after being set, which desideratum is only obtained by the ordinary wooden pole after it has been in the ground for at least a year. A recent test is said to have shown the great strength of the pole, as a heavy No. 6 government wire was strung and the pole subjected to the greatest possible strain, but without moving it in the least.

A HOOP DRIVING MACHINE.—One of the latest novelties in the way of invention is a hoop driving machine. It has been in practical use for several months at the Export Oil Works, Point Breeze, Philadelphia. The machine, as illustrated, is quite curious, but not intricate. The harrel, when "set up," is placed in a horizontal position in the machine. As soon as the machine is started the opposite disks or heads of the harrel approach the machine and are fixed in position, when a series of drivers are pressed down upon the hoops from either end of the barrel, until all are driven to their proper position by pressure only. One machine will head and hoop 1200 barrels per day of 10 hours. Economically considered the machine is said to give good satisfaction. The cost of tenders and eteam for running the machine one day is \$9. The cost of doing the same work by hand in the ordinary way is \$35.

DOUBLE RAILS.—According to the *Joliet (Ill.) News*, the Joliet Steel Co. now roll steel rails in 2-rail lengths, thus saving two crop ends on every two rails, as well as securing a larger product than by the old method of rolling single rail. The company intend to roll 4-rail lengths after a while. The rails are passed through the rolls by machinery.

ROLLER SKATE PATENTS.—Since New Year's Day 150 inventions have been filed in the Patent Office relative to roller skates. Box-wood, of which the wheels are generally made, has doubled in price. Contracts for 10,000 tons of steel for the skatees have been given out.

SCIENTIFIC PROGRESS.

Government Aid to Science.

Sir Lyon Playfair, in his recent address before the British Association of Science, in Aberdeen, said much that was instructive and suggestive in respect to the progress of science, and the conditions on which it depends. The speaker is one of the few men in the world who has had a training both as a man of science and as a statesman. His early career was that of a chemist, but of late he has been an active and influential member of Parliament, and he at one time held a seat in the Privy Council. It is under such circumstances that he can speak both as a savant and as a statesman.

It is moreover interesting to note, continues *Science*, from which we collate, that the principles which he defends were uttered by Prince Albert in his address at Aberdeen in 1859, and long before by George Washington in his farewell address. Prince Albert laid down the doctrine that science should "speak to the State, like a favored child to its parent, sure of his paternal solicitude for its welfare," and also, "that the State should recognize in science one of the elements of its strength and prosperity, to foster which the clearest dictates of self-interest demand." The words of Washington hardly need be quoted to American readers: "Promote as an object of primary importance institutions for the general diffusion of knowledge. In proportion as the structure of a government gives force to public opinion, it is essential that public opinion should be enlightened."

Sir Lyon Playfair goes back to the Greeks and the Arabs, to remind his hearers that in ancient as well as modern times the encouragement of science has been a duty of statecraft, and with many an intermediate allusion he comes now to the actual state of affairs in the United Kingdom, where the working classes now show a respect for science by selecting as their candidates for Parliament in the next election such men as Professor Stuart, Roscoe Maskelyne and Rucker. Playfair has himself received invitations from working-classes constituencies in a dozen of the leading manufacturing towns.

In confirmation of the views which he advocates, Playfair refers to the action of France and Germany, and in still more emphatic terms to the practice of the United States. In some respects, he says, this young country is in advance of all European States in joining science to its administrative offices. He points particularly to the excellent work of the United States Fish Commission, and makes this amusing comparison of the English and American methods of promoting fisheries. In England there are expensive commissions to visit the coast and question the fishermen; and the fishermen, having only a knowledge of a small area, give the most contradictory and unsatisfactory evidence. "In America, the questions are put to nature and not to fishermen," and the results of the inquiry are therefore far more fruitful. In this bright antithesis—questioning nature, not the fishermen—there is a ready answer to those who wish for "practical" science, not abstract science. It seems "practical" to question fishermen; the process proves to be fallacious. It seems "abstract" to question nature; but this method is found to be the surest road to positive knowledge, and hence to the best results.

The Age of the Mounds.

The recent examination of a great number of mounds and their contents, and inquiries into their history, and surroundings, is gradually leading to a solution of certain archæologic riddles which a few years ago seemed unsolvable. The *Norristown Herald* says:—

While some of the mounds are, doubtless, very ancient, others similar in character and equally interesting have certainly been built up since the advent of Europeans. A string of sleigh bells much corroded, but still capable of tinkling, was found among the flint and bone implements in a mound in Tennessee, while in Mississippi, at the point where De Soto is supposed to have tarried, a Spanish coat of arms in silver, one blade of a pair of scissors and other articles of European manufacture were found in positions which indicated that they were buried by the original builders of the mounds.

In a Georgia mound two copper plates were found, upon which were stamped figures resembling the sculptures upon the Central American ruins. The workmanship is vastly superior to that displayed upon the articles of pottery, stone and bone found in the mounds, and their origin and purpose are not yet explainable. Aside from these plates nothing has been found to indicate a connection between the mound builders and the Aztecs or the Pueblos, while on the other hand, there appear many reasons for not going beyond the Cherokees and their fellow red men of the Ohio and Mississippi valley to find the origin of these curious erections. The purpose of the mounds still remains in some cases a mystery, but in others they are known to have been made sometimes for burial places, and sometimes as foundations for Indian villages secure from the floods to which the low lands were periodically subjected.

THE story of the Pennsylvania meteorite, to which we alluded in our last issue as having fallen and been found where it struck the earth

near the West Virginia State line, proves to be true only so far as it was of extraordinary size and was distinctly seen in its flight. It appears that Professor Langley, of the Allegheny Observatory, sent out a competent party to investigate into the fact of the finding and nature of the celestial visitor. This person has returned, and reports that the reported finding of the huge meteorite "fifty feet in diameter" is merely a fiction of the news gatherers.

MIND CURE, just at this time, is attracting considerable attention in this city and elsewhere. The relation of the mind to the body is as yet but very imperfectly understood, although it is undoubtedly a matter of great importance, both in an economical and scientific point of view. Mind cure is a thing about which not much is known, although there is abundant evidence that it has a basis in truth. In regard to it an exchange says: "There are certain diseases which are real and yet which can be cured or brought on simply by a certain condition of mind. As a man thinketh in his heart so is he," has in it much of truth. Learned men who do not make a business of this mind cure, who have other work, and who take it up simply as a recreation, have in some cases produced wonderful results. Every doctor has patients whom medicine will not reach, and who can be reached only by creating a condition of mind favorable to a cure. Prof. E. P. Throing, of New York, of the Academy of Science, carried on studies along with Dr. Geo. M. Beard before his death. Dr. Throing can sometimes simply by looking at a patient work a cure. He has been known by a glance of the eye to render one insensible to pain, so that the most difficult surgical operation could be endured without suffering, and to cure the most difficult cases of sciatica, when the limb was stiffened, simply by rubbing it and saying the pain had left. There are so many cases recorded where cures have been wrought that there can be no question but that mind cure has to it a basis of truth. It is also quite likely that some of the so-called faith cures are nothing but mind cures. We believe that whatever of truth there is to this thing will be carefully looked into by men of science and made use of for the good of the race."

FOSSIL INSECTS OF THE COAL DEPOSITS.—At the recent meeting of the Manchester Geological Society, a paper from M. Charles Brogniart, of Paris was read by Mr. M. Stirrup, on "The Fossil Insects of the Primary Group of Rocks: a Rapid Survey of the Entomological Fauna of the Paleozoic Systems," which was illustrated by photographs and drawings of insects found in the coal measures of the mines of Commeny (Allier). With regard to some of these insects, Mr. Stirrup remarked that there were none now in existence which were so large, and that if the forests of the coal era were not vocal with the song of birds, they were certainly vocal with the buzz of gigantic insect life. In reply to a question, Mr. Stirrup remarked that he felt certain specimens of these insects might be found in the Lancashire coal measures, if they were looked for; the insects of which they had seen illustrations, were found in the shales, such as occurred on the roofs of their own coal mines. Mr. Dickinson observed that if they were to accept the assumption that these insects were or had been amphibious, a great many difficulties would be got over as to the formation of the rocks; he had never yet met with a single fossil of any animal which had not at some period of its life had a water habitat.

FORMATION OF FOG.—The experiments of Coulter and Mascart, extended by Aitkin, have demonstrated that in a perfectly moist air no formation of fog is possible, however much the temperature is lowered, so long as the air is absolutely free from dust, and that the more air, sufficiently moist, is charged with such foreign particles the more intense is the formation of fog under a sufficient lowering of the temperature or pressure of the air. Let filtered and completely moist air in a glass ball have its pressure diminished, then will only a few particles of fog reveal themselves to the most careful inspection, even under the powerful light of an electric lamp—particles of fog, which, moreover, yield not the slightest colored image. Admit now into this filtered air a few cubic millimeters of ordinary house air, then will a very fine, silvery, transparent fog at once form itself, of such slight density that even in the case of considerable area of it the transparency of the atmosphere would be but very little affected. At the first moment of its formation let a reflected image of the sun, or the reflected light of an electric lamp, be viewed through it; the image will be seen surrounded by an intensely luminous blue or greenish light.

A NEW USE FOR SULPHUROUS ACID.—A new process for preparing chemical fiber by the use of sulphurous acid has been patented. It is intended also to prepare vegetable fiber for spinning and other uses, eliminating the silica and other incrustating substances that bind the fiber together. The principal feature of this process is the treatment of vegetable fiber with a solvent containing hydrofluoric acid and sulphurous acid.

MAJOR POWELL, chief of the Geological Survey, has discovered in New Mexico, near California Mountain, what he pronounces to be the oldest human habitations upon the American continent.

SAN FRANCISCO:

Saturday Morning, Nov. 7, 1885.

TABLE OF CONTENTS.

EDITORIALS.—Reading for Mining Camps; The Tustin Ore Mill; Distribution of Ores; Agents and Correspondents, 305. Passing Events; Agricultural or Mineral Lands; Burning Quartz Before Crushing; Dumps; Academy of Sciences, 308. The Philadelphia Cable Road; Single-Acting Engines; The Ovar D'Alene Mines, 309.

ILLUSTRATIONS.—The Improved Tustin Ore Mill, 305. Improved Design for Single-Acting Engines, 309.

CORRESPONDENCE.—Notes from the Interior; Calaveras County Mines, 306.

MECHANICAL PROGRESS.—The Results of Improved Machinery; Blasting Cast Iron; Iron Telegraph Poles; A Hoop Driving Machine; Double Rails; Roller Skate Patents, 307.

SCIENTIFIC PROGRESS.—Government Aid to Science; The Age of the Mounds; Mind Cure; Fossil Insects of the Coal Deposits; Formation of Fog; A New Use for Sulphuric Acid, 307.

USEFUL INFORMATION.—A New Substance for Mirrors; Solder for Glass and Porcelain; How to Keep Chestnuts Soft and Sweet; Brazing; The Largest Block of Marble on Record; Polishing Powder from Ashes; Some Things Worth Knowing; A Type and Stereotype Setting Machine; A Superior Blotter, 307.

GOOD HEALTH.—Hot Water in Dyspepsia; Raw Potatoes for the Complexion; What Shall We Drink? The Hypodermic Needle; A New Cloth for Rheumatism to Wear, 311.

MISCELLANEOUS.—Gold and Silver Bullion, 306. Practical Hydraulics, 310.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, New Mexico, Oregon, and Utah, 312-14.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 316.

Business Announcements.

Centrifugal Roller Quartz Mills.—F. A. Huntington, S. F. Delinquent Notice.—Orelands Mining Co., S. F. Situation Wanted.—Pacific Iron Works, S. F. Pipe Tongs.—Henry F. W. Solist, S. F. Risdon Iron and Locomotive Works.—S. F.

See Advertising Columns.

Passing Events.

The first good rain of the season fell this week, and prevailed over a large area. This will raise the rivers enough to put a stop to river-bed mining for this year.

Preparations for winter are going on in most of the mining camps, and in the more mountainous ones to the north some mines are now shutting down.

From various points comes word that old and abandoned mines are being taken up and reworked. In some places they are striking deeper in old mines, the experience of some of our best gold mines being that they are as rich deep down as at the surface.

A number of very good strikes have recently been made in different parts of this State. Gold quartz mining is experiencing something of a revival.

OLD MINES.—An effort is being made to resuscitate many of the long-abandoned mines, in Nevada county, which have never been worked below a 500-foot level. The experience of the Idaho, Eureka, Empire and North Star proves conclusively that deep workings are the most profitable. The trouble has been that many of the mines were originally equipped with too light machinery, and the owners were unable to contend with the body of water met at from 300 feet to 500 feet below the surface. Unwilling or unable to meet the expense caused by flooding, they abandoned their claims, and new parties are reaping the rewards.

Agricultural or Mineral Lands.

Some time since several Portuguese and Italian farmers in Santa Clara county, who claimed that the land near the Guadalupe mine was more fit for agriculture than mining, received rather a setback by the Commissioner of the General Land Office confirming the Register and Receiver's action, adjudging the land to be mineral. Nevertheless, the farmers appealed to the Secretary of the Interior, the only question in the case being whether the land involved was more valuable for mineral purposes than for agriculture. The testimony was voluminous and exhaustive, numbers of the witnesses being farmers with no mining knowledge whatever. A portion of the land had even been applied for by parties under the pre-emption and homestead laws, and one farmer had even received an agricultural patent. The Santa Clara Mining Association, of Baltimore, owning the Guadalupe mine, was therefore compelled to begin a contest against the agricultural claimants.

The testimony shows that the lands in question are located about 60 miles southeast of San Francisco, within a few miles of the city of San Jose, in Santa Clara county, adjoining the Capitancillos creek, and stretching out in a southwesterly direction therefrom, embracing 957.32 acres. That the country is rough and mountainous, cut into by numerous deep, precipitous gulches and canyons, and covered to a great extent by dense brush, chaparral and scrub oak. That there are occasional patches of fairly good soil, varying from one to twenty acres in extent, but that the great mass of the soil is thin and unfit for cultivation. That the land is situated in a mineral belt embracing within four miles the "Guadalupe," "New Almaden" and "Henriquitia" quicksilver mines, all noted for the amount of quicksilver produced from them. That immediately to the northeast of said lands lies the Guadalupe mine, also the property of the Santa Clara Mining Association. That from said Guadalupe mine there extend in a southwesterly direction, three distinct ore-bearing zones penetrating and passing through said section 30 of the lands in controversy. That several of the tunnels of the Guadalupe mine penetrate lots 7 and 8 of said land to a distance of 300 or 400 feet; that many carloads of cinabar have been taken from these tunnels, and that within 10 years some 40,000 or 50,000 flasks of metal have been taken from the lands south of the Capitancillos creek. That the company has spent \$1,500,000 on its whole claim, and that \$100,000 of that sum have been expended in developing the mineral resources of the public land in question. Some 17 witnesses including civil engineers, surveyors, mining experts, practical miners, assayers, mining engineers, the Deputy County Assessor, and neighboring farmers, all acquainted with the land, testified, on the part of claimants, that the formation of these lands is similar to that of the surrounding mineral bearing lands; that numerous specimens, produced in evidence, from croppings in various parts of section 30 and 31, contained mineral, or indications thereof; that each lot and each 10 acres of each lot is more valuable for mineral purposes than for agriculture, and that, as a fact, agriculture had been prosecuted thereon to a very limited extent.

The witnesses on the part of contestants were principally neighboring farmers, none of whom claimed to be mining experts. Their testimony is to the effect that several tracts have been cleared and cultivated; that much more of the land is fit for cultivation, and is more valuable for agriculture than for minerals.

It is urged, in view of the fact that this land adjoins certain quicksilver mines, that it would have been worked long ago if it had any mineral value, and that the bad faith of the company in this matter is shown by the fact that they have so failed to work said land. The Secretary of the Interior states that this would be a weighty objection were it not for the further fact that for the past seven or eight years the company has been actively engaged in developing the mineral resources of these lands and the lands immediately adjoining them on the northeast. After bringing forward these points the Secretary of the Interior decides that the testimony is conclusive that the land is more valuable for minerals than for agriculture, and affirms the first decision of the Commissioner of the General Land Office.

Burning Quartz Before Crushing.

In the gold mining district of Maldon, colony of Victoria, it is the general custom to burn the quartz before crushing, in order to extract the sulphur from the pyrites to render amalgamation possible. At the Grand Junction Company's works there are four kilns for burning the quartz as it comes from the mine, a description of which will interest miners here who have sulphuretted ores. These kilns adjoin each other and are built up with strong, dry stone walls in the following manner: A cutting or hench is made into the face of the hill, and the wall is built at the front side and ends, high enough to admit of the whole length of the kiln being built between the front wall and the side of the cutting already made, having openings in the front wall opposite the places where the kilns are built, to haul out the quartz to take it to the battery. Circular kilns are built in the shape of an inverted cone, as close to each other as the walls will admit. These are capable of holding and burning 50 tons each. The bottom of the kilns is sufficiently high above the tramway, which runs along the front, to allow the burnt quartz to be hauled out into the trucks.

Before commencing to put the quartz into the kilns, there is a good layer of firewood placed in the bottom; then a layer of quartz, next a layer of firewood; afterwards quartz again, and so on until the kiln is filled; but in filling the kiln, firewood is set on and all around its sides, and quartz hooped up on top as much as possible, after which the fire is kindled at the bottom, and the kiln kept burning from seven to eight days. By the end of this time the quartz is tolerably well calcined, especially near the bottom of the kiln, where it is run together like slag. The manager of the company states that the cost of this process amounts to about four pence per ton, and he contends that, irrespective of the cost of liberating the sulphur and arsenic, it pays the company to roast the quartz in this manner, as the amount of work done by the battery is greatly increased, owing to the quartz being more friable. In this he is no doubt correct, as those who have burned quartz before grinding it in arastras can testify.

After the burned quartz is taken out it is crushed in an ordinary battery, but no quicksilver or copper plates are used on the riffle tables, they being simply covered with blankets. At the end of the blanket tables the tellings run into Chili mills and are ground up with quicksilver, after which they run over rocking tables, also covered with blankets.

There has been considerable discussion in Australia on this subject, and it has been one of the subjects of inquiry of a Government Board. From the evidence they obtained it would seem that crushing pyritous quartz raw is the more advantageous method, and the testimony of mine managers was corroborated by professional evidence on this point. It is asserted that it would be impossible to thoroughly oxidize the sulphur by burning, and that a lower sulphide would result, which would melt and enclose the fine particles of gold, rendering their subsequent extraction more difficult. The evidence of one gentleman of a practical nature, was to the effect that the roasting has the effect of converting the gold on the exterior of the quartz into globules and covering them with ferruginous glaze, which is prejudicial to the proper extraction of the precious metal. This gentleman had microscopically examined raw and burnt quartz washings from the lowest blankets, and found most particles of gold in the latter.

Some persons examined by the Board of Inquiry advocate the burning, not because they believe it to be the more efficacious method but because of less wear and tear of machinery, and by such a method more quartz can be crushed in the same time. Some considered that many substances are removed during the process of roasting which would tend to interfere with amalgamation, and that the loss of mercury is less. Others think that fine gold is run into a globular form during roasting and is more easily saved. On the other hand, one manager of a large company said he would burn the quartz previous to crushing if the pyrites were not to be saved, but if they were needed he would crush raw. After a careful consideration of this portion of the questions, the Board was of the opinion that crushing raw is the best method of treatment, except where

pyrites are absent; then burning might be adopted if fuel is easily obtainable, in order to economize wear and tear in crushing.

Dumps.

There is no doubt that during the days when mining and milling was carried on more carelessly than it is at present on this coast, a great deal of pretty good ore was thrown over to the dumps. In the hurry and push of those times there was much waste of all sorts of things. In some cases the miners were to blame, in others the managers. To get a good high average of ore, considerable that would pay, but was not rich, was thrown away. But in these days of cheaper milling this ore would pay well. It is all on the surface and needs sorting only from the real waste. In some of the larger camps, like the Comstock, Eureka and some other Nevada mining regions, many of the dumps have been sources of profit to those who have picked them over. This has also been the case in this State. No doubt it would pay many persons better than prospecting to get permission to work over old dumps at mines where large quantities of material have been extracted.

A useful lesson is taught to miners in this connection by an event at the McBride mine, east of Benton, Mono county, in the White mountains, as told by the *Inyo Independent*: A large amount of ore lay on the dump at this mine for a long time. This ore was thought to be of very little value, and no attention was paid to it. H. H. Russell, Superintendent of the Mountain Queen mine, in the same neighborhood, at length had his attention called to the dump. Mr. Russell is not an elegant gentleman, but a practical miner, who lets nothing about a mine escape his observation, and will not take gossip for facts. He prospected the supposed worthless dump, and then made an offer of \$900 for the lot. This was like finding so much money, and the offer was accepted. A small two-stamp mill stands near the dump; with this Mr. Russell went to work on the ore. In three weeks' run of the mill \$1800 in gold was got from the worthless dump. Mr. Russell finds that there is ore enough in the dump to keep the mill running steadily eleven months, and is satisfied that it is all as good as that already milled. Here is a lesson for miners to be careful about what they throw on the dumps.

Academy of Sciences.

Dr. Harkness was in the chair at the last meeting of the California Academy of Sciences.

The following donations to the museum were acknowledged as received: Timber destroyed by the tereid in seven months, taken from San Francisco bay and presented by Marsden Manson; hydroid from the ship Earl of Dalhousie, donated by Mr. Buckminster; section of a log of driftwood found at Cape Lishurne, Alaska, 60 degrees north latitude, and supposed to have drifted from the Yukon river, donated by Professor Davidson; specimens of limestone, iron ore and serpentine from Alta, Placer county, presented by A. Larsen; *Nepenthes distillatoria*, or pitcher plant, presented by Captain R. W. Simpson. A few remarks were made by Dr. Behr upon the secretion of pepsine by the *Nepenthes*, and also upon the subject of carnivorous plants.

Mr. Charles Burkhalter, of Oakland, read a note on the new star in Andromeda. A change was noticed in the star on Oct. 26th, and on the 27th, under most favorable circumstances, the star was found after much search to be of the eleventh magnitude. He made arrangements with Mr. Hill, who is in charge of the Davidson observatory, to take simultaneous observations. A letter had been received from Mr. Hill, and was read, in which he reported the star Nova Andromeda as of the twelfth magnitude on October 27th when he observed it.

Captain Churchill exhibited a new chart for the use of mariners, which he had invented. Edward Stephens Clark was proposed for membership.

The famous Allison ranch mine, Nevada county, produced under the original management \$2,800,000, but was abandoned when the pay streak ran out. It was subsequently worked, but at a loss. Recently it was handed to a French company, and it is intended to work it deeper than the 500 feet already sunk.

The Philadelphia Cable Road.

On Oct. 24th, a severe accident occurred on the Philadelphia Cable road, seriously injuring three persons—one fatally, and killing one horse. It occurred at Forty-second and Market streets, where there is a turn table for the traction cars. There are usually a number of cars standing in a line awaiting their turns, between Forty-first and Forty-second streets, as happened shortly after 6 o'clock on that evening. There were also a number of horse cars on the curve leading to Forty-first street. Several of these cars contained passengers going to other parts of the city. At that moment traction car No. 103 came up Market street and was released from the grip, the car coming to a stand still. Just after the passengers alighted, there was a shock that threw the grip man and conductor off their feet. The car shot forward as though it was struck by a cyclone, tearing through the transfer car, which it tossed in the air. The horse attached to this car was crushed and killed. Several other cars were smashed, including the one filled with passengers, four of whom were seriously injured. Finally the grip broke, and the tearing car came to a halt.

The cause of the accident was: A strand of the cable became detached and caught in the grip, which is a very imperfect and crude affair. It is something in the shape of a grip formed by a human hand, with no device for throwing out the cable in case of a strand catching, like the San Francisco roads are provided with. The Philadelphia grip is not only liable to injure the cable, but is subject at any time to the same kind of an accident, and should the grip get foul when the car is running through a crowded thoroughfare is liable to cause a great loss of life and property.

In all the experience of cable road in this city, no such accident as that reported in Philadelphia ever occurred here. The Philadelphia company appears to have made mistakes from the start, not being willing to take advantage of the experience of the roads in this city, but wanting "something new and better," which they claimed for their system, and because it did not cost much for patent rights, the latter evidently being the principal reason for not adopting the successful system in use in this city.

Such a system of cable roads as they are attempting to run in Philadelphia is not only dangerous to life and property, but seriously injures the cable system when it is attempted to be adopted in other cities. The New York Times, which appears to be in the interest of elevated or horse roads of that city, and opposing the adoption of the cable system, always refers to the Philadelphia failure. In referring to this accident, the Times says, "For many months a cable company has been trying to operate cable roads in Philadelphia. Thus far these roads have been a nuisance. The streets of which the company took possession have been in a condition of chronic upheaval." This refers to the constant tearing up of the streets to alter the tube, which was so imperfectly constructed that the slet cannot be kept open.

We would advise our Eastern friends who propose constructing cable roads, to send their engineers here and profit by the experience of the successful roads in operation in this city, or what is better still, get engineers from here to build their roads for them.

FIVE tunnels are to be run this winter on leads situated in Sheep mountain district, upper Emigrant gulch, Montana.

Single Acting Engines.

Mr. J. Richards, the talented superintendent of the San Francisco Tool Company, has recently received through the MINING AND SCIENTIFIC PRESS Patent Agency patents covering several improved designs for single acting engines. The San Francisco Tool Company are the only makers of these engines on this coast. The engravings on this page give an idea of the general design.

Engines of this class are now extensively employed for all kinds of purposes both in this country and in England, where they have been in regular use for 12 years past. They are in most respects a plain steam engine, without other novelty than having an extra cylinder and piston. They require no oiling, packing or adjusting like common engines, and cost no more, according to their power.

The high speed of the engine dispenses with gearing and belts for pumping, the engine being connected directly to the pump shafts. The shafts of the engines are made of steel and the connections of bronze. The valves are, in most

will receive more attention. Those who wish to pursue the subject may find some information relating to it anticipated in the MINING AND SCIENTIFIC PRESS of April 10, 1875.

The Coeur D'Alene Mines.

[Written by our Special Correspondent R. G. HUSTON.]

The Coeur D'Alene mines are situated in the range of mountains of that name, 33 miles southwest of the station of Thompson Falls, on the North Pacific Railroad, now reached by hiring saddle horses from that place. The road in is very rough, although some enterprising individual has a lien on it in the shape of toll, and from the amount of corduroy bridges he had to build to make it passable, I think he has amply earned all he charges for traveling over his road. Fifty cents is the assessment. There will be undoubtedly a good road from that point in, as there is some very heavy machinery to be transported soon for the Plume Company.

There is another way of getting in, but it is not the popular one: by getting off the N. P. R. R. at Spokane Falls and staging for 35 miles

militated against the best interest of it in a great degree. It was located in 20-acre lots, and Government patents were issued for it, and many of these were owned by ranchmen from the Palouse valley, and they would neither do anything themselves or permit anyone else unless they were paid a fabulous sum for their locations, something that men of means are not prone to do in an unprospected mining camp. They did not, in many instances, go through the preliminary formality of sinking down and striking a discovery.

The placer mines that have been developed, and are now working, are all within a radius of 10 miles of Murray. As a natural consequence that is the main distributing point for the different mines. During the first excitement the town of Eagle City was built up, but as the placer developments that were easy made were some four miles further up the main creek, Murray was started and is now the town of the miners. It is also the county seat of Shoshone county, Idaho.

There has been considerable prospecting done and parties have satisfied themselves that there is a channel of pay running along the hill north of the town. There was a small ditch taken on this last season. One or two companies have worked their ground with good results, notwithstanding the fact that they have to cribb their tailings, an expensive luxury in this county where timber is plenty—so much so that it is greatly in their way.

The results have been so satisfactory that a company has organized to bring in a large ditch. The sides of the gulch are of such a loose, shelly formation that they are compelled to flume it all the way. This will be finished by another season, and will doubtless give remunerative employment to a large number of men. On Eagle creek, which is some 12 miles long, there are about 25 men at work up near the head of it. It is at the junction of this creek that Eagle City is located. Thence up the creek comes the Cumber gulch. Occident and Octon have all been worked. Then we come to Dream gulch, out of which there was some very good pay taken. This is noted for the largest nugget that was ever taken out in the camp, weighing nearly 20 ounces. It is also the location of the Buckeye Boy lode, of which more anon.

The next is Missoula and Buckskin, both of which have yielded good pay. Vestal's claim in Buckskin in particular is paying over one ounce a day to the hand, which is good enough to make an old miner's mouth water, although I doubt if Vestal will clear the

amount of hard coin out of it that he did out of the Penobscot mine, some 20 miles from Helena, which he discovered some years ago. As we continue up the creek there are more, such as Nugget, Alder, Gold Run, Cougar, Wasp and Reeder gulches, all of which have been and are being worked.

Then on the south side, from Murray over the divide and tributary to Beaver creek, are a number of others. Trail gulch being open in a number of places, and in some of them paying handsomely, Frank Gordon, the week I was there, with one man and recker cleaned up 12 ounces, which I call a pretty good starter for a placer claim.

There are two little towns located on these Beaver creek mines. Delta is at the junction of Trail gulch and Beaver creek, and is quite a promising little town. Another season when there is plenty of water, no doubt it will be a prosperous place; and Myrtle is the same distance up Trail gulch and the junction of Placer gulch.

There are just now many of the miners who have locations in this locality at work for the Plume Company, for the reason that they cannot work their own grounds for want of water. Potosi gulch is also being worked to some extent. The whole country is so densely wooded that the only way you can get through, except on the trails that are cut out, is to go about and then sometimes it is almost impassable. Gold is said to be "where you find it." My experience teaches me that it is found in some very tough places to get at, but the average miner and prospector is a persevering individual and "he gets there."

(To be Continued.)

IMPROVED DESIGN FOR SINGLE-ACTING ENGINE.

cases, placed outside the main frame and accessible. The cylinders are jacketed, and every precaution taken to save steam and cost of running. The position of the valves and their working is not concealed and inaccessible, but in sight and adjustable. The wear of the valve and also of its connections can be taken up, otherwise the position would soon be lost. The crank cases contain nothing but the cranks and piston connections, no governor eccentric or other parts to break or come loose. The engines have no eccentrics, in the common sense of that term; the valves are driven by cranks, as shown in the engraving. The steam valve is free to wear to its seat, as in the case of a common slide valve, and will not leak from wear. Piston valve engines are furnished, in some cases, for very high speed and intermittent duty, and where engines are exposed to dust and grit; but are not recommended where oscillating valves will suit as well. Single acting engines will, it is thought, in the near future, take the place of the double acting type in most cases where condensing apparatus is not wanted. They should be examined by everyone desiring to erect steam power.

METALLIC SULPHIDES.—In the PRESS of Sept. 5th we gave some valuable information relating to the oxidation of metallic sulphides. The process rests on scientific data, and no doubt

to the Coeur D'Alene lake; thence by steamer 60 miles, and then stage again for 35 miles, making a tedious two or three days' trip; the preference of the traveling public is surely in favor of the Thompson Falls route.

The main camp lies on Pritchard creek, and so far as I am now capable of judging, has been as much misrepresented a camp as I have ever seen, for the reason that discouraging and conflicting reports have been all that the outside public have seen. To be sure, the first excitement was almost without foundation, and men from all parts of the Union rushed in there in the dead of winter when the whole country was covered with 10 feet of snow, and from all accounts were expecting to scratch away the snow and find nuggets of gold the size of a water bucket, and, of course, they were disappointed. Some had some means, others had none, and the consequence was that nearly all of them left disgusted, and consequently gave the country a black eye. In all candor they believed that they were truly stating the facts, but a few persevering, patient workers remained and their efforts have been rewarded by developments that I am sure will make it a remunerative camp for years to come. There are already quite a number of placer claims that are paying their owners handsomely. The manner in which the camp was located has in my mind

PRACTICAL HYDRAULICS.

NUMBER 5.

PRINCIPLES OF HYDRAULICS.

[Written for MINING AND SCIENTIFIC PRESS by P. M. RANDALL.]
[COPYRIGHTED.]

Making $b=ph$, $t=0$, that is, closing the top of the weir, at the level of still water, and equation (46) becomes

$$Q = \frac{gpc}{15} (2g)^{\frac{1}{2}} h^{\frac{5}{2}} \text{ cubic feet.} \quad (48)$$

Comparing equations (48) and (34),

$$Q:Q::\frac{g}{48}:\frac{g}{34}::\frac{h}{15}:\frac{h}{15}::3:2. \quad (49)$$

Equation (49) shows that, with respect to two triangular weirs of equal size, that the discharging capacity of the weir whose top is closed at the level of

still water, as E in Fig. 6, is, to the discharging capacity of the weir whose top is open, as AB in Fig. 5, as 3 is to 2, or 1.5:1. Table 4 was computed from an open weir, as ABC, Fig. 5. To render it applicable to a closed weir, as DEF:

Rule 16.—Multiply the tabulated flow due any head given in Table 4 by 1.5.

Ex. 26.—In a trapezoidal weir, the head between the crest and the level of still water being three (3) inches, the length of the crest two (2) feet, and the width of the opening at water level one and three-fourths (1.75) feet, what is the flow in cubic feet per second when the coefficient of discharge is .62?

Cal.—Head 3 inches = $\frac{1}{4}$ feet.

By formula (47), $(\frac{1}{4})^{\frac{3}{2}} = \frac{1}{8}$.

Three times bottom width: $2 \times 3 = 6$.

Twice top width: $1.75 \times 2 = 3.5$.

Whence, $1.07 \times .62 (3.5 + 6) \frac{1}{8} = .7878$ cubic feet.—Ans.

Ex. 27.—In a trapezoidal weir, the head being twelve inches, the bottom width three feet, the top width one foot, and the coefficient of discharge .624, what is the flow of water over it in cubic feet per second? By formula (47).

Cal. 1st.— $1.07 \times .62 (1 \times 2 + 3 \times 3) \times 1 = 7.3445$ cubic feet.—Ans.

Cal. 2d.—Observe that the weir opening, ACDB, Fig. 4, is resolvable into two parts, to wit: the part CDBE, which is equal to the rectangle CDGF, and the triangular part ACE, whose crest is AE, and whose top is closed at C, at the level of still water. Applying, in Example (27), Table 2, to the rectangular part CDGF, substituted for the part CDBE, and Table 4, to the triangular part ACE:

By Table 2, due one foot head, one foot crest, 3.3390 cubic feet.

By Table 4, due in quadrantal weir with open top, 12-inch head, 2.6365.

By Rule 16, $2.6365 \times 1.5 = 3.9547$.

Hence $3.3390 + 3.9547 = 7.2937$ cubic feet.—Ans.

The discrepancy between calculating 1st and 2d arises from Table 4, in the computation of which .616 on the authority of Prof. Thompson, was employed as the coefficient of discharge, instead of .624, as proposed in the given example.

FLOW OF WATER OVER A RECTANGULAR WEIR, HAVING ITS ANGLES, HORIZONTAL AND VERTICAL, AND ITS UPPERMOST ANGLE ON THE LEVEL OF STILL WATER.

Fig. 7.

Let ABCD, of Fig. 7, represent a rectangular weir, having its vertical angle C, at the level of still water. Through C, draw a horizontal line indefinitely. Produce AB, AD, intersecting this horizontal line in E and F. Draw AG = h perpendicularly to EF, and bisecting A.

Let AB = m, and AD = n. It is obvious from the imposed conditions, that AE = AF = m + n; that EF = 2GE = 2GF = 2AG = 2h; that FD = DC = AB = m, and BE = BC = AD = n.

Observe that in Fig. 7 are represented three open

quadrantal weirs, FAE, FDC and CBE, and that the given rectangle ABCD = FAE + FDC + CBE. (50)

Denote by Q_u the flow of the given rectangular weir.

By similar triangles, find the heads or depths as follows:

$$PD = \left\{ \frac{mh}{m+n} \right\} \quad (51)$$

$$LB = \left\{ \frac{nh}{m+n} \right\} \quad (52)$$

Substituting these values, and the value of AG = h in (34), noting that for quadrantal weirs, $p=2$,

$$Q_u = \frac{g}{15} c (2g)^{\frac{1}{2}} \left\{ 1 - \left\{ \frac{m^{\frac{5}{2}} + n^{\frac{5}{2}}}{(m+n)^{\frac{5}{2}}} \right\} \right\} h^{\frac{5}{2}} \quad (53)$$

If in (53), the general formula for the flow of water through a rectangular weir having its uppermost angle vertical at the level of still water, we make m equal n, and substitute the value of $(2g)^{\frac{1}{2}} = 8.025$, and $c = .616$,

$$Q_u = 1.70435 h^{\frac{5}{2}}. \quad (54)$$

In which case the rectangle becomes a square, as represented in Fig. 7, by AIGN.

Comparing formula (54) with formula (35), which is for the flow of water over a quadrantal weir, we have:

$$Q_u = \frac{1.70435}{2.6365} = .6464 Q. \quad (55)$$

To determine the flow of water through a square weir, having its uppermost vertical angle at the level of still water.

Rule 17.—According to formula (54), multiply the square root of the fifth power of the head or depth by 1.70435; or by formula (55), multiply the flow in Table 4 for the given head by .6464.

Ex. 27.—The head being 3 inches = $\frac{1}{4}$ foot in a rectangular weir, having its upper most vertical angle at level of still water, what is the flow in cubic feet per second?

Cal. 1st.—By formula (54).

Fifth power of the square root of $(\frac{1}{4})^{\frac{5}{2}} = \frac{1}{32}$.

$1.70435 \times \frac{1}{32} = .05326$ cubic feet.—Ans.

Cal. 2d.—By Rule 17, second part.

By Table 4, flow due $\frac{3}{4}$ -inch head = .0824. Then $.0824 \times .6464 = .05326$ cubic feet.—Ans.

Ex. 28.—The sides of a rectangular weir, with its angles vertical and horizontal being 2 feet and 1 foot, the coefficient of discharge being .62, what is the flow per second?

Cal.—Employ formula (53).

Taking the given data $m=2$, $n=1$,

Then $m+n=3$, and (see Fig. 7),

$$AG = h = \left(\frac{m+n}{2} \right) \sqrt{2} = \frac{3}{2} \sqrt{2} = 2.12127 h^{\frac{5}{2}} = (2.12127)^{\frac{5}{2}} = 6.55376.$$

By Table 5, $m^{\frac{5}{2}} = (2)^{\frac{5}{2}} = 5.657$; $n^{\frac{5}{2}} = (1)^{\frac{5}{2}} = 1$.

By Table 5, $(m+n)^{\frac{5}{2}} = (3)^{\frac{5}{2}} = 15.590$.

Substituting these values of $m^{\frac{5}{2}}$, $n^{\frac{5}{2}}$, $(m+n)^{\frac{5}{2}}$ $h^{\frac{5}{2}}$, $(2g)^{\frac{1}{2}} = 8.025$, and $c = .62$. $Q_u = \frac{g}{15} c \times .62 \times 8.025 \left(1 - \frac{5.657+1}{15.59} \right) 6.55376$.

Whence $Q_u = 9.9644$ cubic feet.—Ans.

FLOW OF WATER THROUGH CIRCULAR AND SEMI-CIRCULAR WEIRS.

Fig. 8.

Fig. 9.

Fig. 10.

Let Figs. 8, 9 and 10, represent respectively the circular and semi-circular weirs, Fig. 8 touching the water surface at A, Fig. 9 in a similar manner at B, and Fig. 10 at its diameter CD.

Let r feet denote the radius with which the several weirs are described, then in both Figs. 9 and 10 will r denote the head, while in Fig. 8 the head (maximum) will be 2r.

Let x in Fig. 8 denote any portion of the head, and

Q , the flow in cubic feet $(2g)^{\frac{1}{2}}$ to acceleration of gravity, and c coefficient of discharge.

$$\text{Then } dQ = 2c (2g)^{\frac{1}{2}} 2 (r)^{\frac{1}{2}} \left(1 - \frac{x}{2r} \right)^{\frac{1}{2}} x N dx. \quad (56)$$

Integrating (56) between limits of $x=0$, and $x=2r$, and substituting the value of $(2g)^{\frac{1}{2}} = 8.025$,

$$Q = 24.2129 C r^{\frac{5}{2}}. \quad (57)$$

Let Q_2 = the flow in Fig. 9 per second. Integrating (56) between limits of $x=0$, and $x=r$, there results the flow in that portion of Fig. 8 represented by FAE, which is equal to HBG, Fig. 9, the discharge sought, viz.:

$$Q_2 = 9.2313 C r^{\frac{5}{2}}. \quad (58)$$

Again in Fig. 10: Let x denote any portion of the head from A, and Q_3 the flow in cubic feet per second; Then

$$dQ_3 = (2g)^{\frac{1}{2}} (r^2 - x^2)^{\frac{1}{2}} x dx. \quad (59)$$

Integrating (59) between limits $x=0$, and $x=r$, and substituting value of $(2g)^{\frac{1}{2}} = 8.025$,

$$Q_3 = 7.6932 C r^{\frac{5}{2}}. \quad (60)$$

Comparing equations (60) and (35) and making $c = .616$, and $r = h$,

$$Q_3 = 1.79 Q. \quad (61)$$

To find by Table 4 the flow through a semi-circular weir: Open at the top as represented by CD Fig. 10.

Rule 18.—Multiply the flow in Table 4 for the given head or radius by 1.79. See formula (61).

The triangle CA₂D, inscribed in the semi-circular weir, Fig. 10, represents a quadrantal weir whose flow is Q , while the flow of the semi-circular weir CA₂D is Q_3 .

Comparing equations (58) and (35) and making $c = .616$, and $r = h$,

$$Q_2 = 2.1568 Q. \quad (62)$$

To find by Table 4, the flow through a semi-circular weir closed at the top, as represented at B Fig. 9.

Rule 19.—Multiply the flow in Table 4 for the given head on radius by 2.1568 (62).

To find by Table 4 the flow through a circular weir touching the water surface at A as represented in Fig. 8.

Comparing equations (57) and (35) and making $C = .616$, and $r = h$,

$$Q = 5.6566 Q. \quad (63)$$

Rule 20.—Multiply the flow in Table 4 for the head or depth equal to the given radius of the circular weir or opening by 5.6566. See formula (63).

Ex. 29.—In a semi-circular weir, with open top, as represented by Fig. 10, the head on radius is ten inches. What is the discharge in cubic feet per second?

Cal.—By Table 4 the flow due a head of 10 inches is 1.6713 cubic feet.

By Rule 18 we have—

$1.6713 \times 1.79 = 2.9916$ cubic feet.—Ans.

Ex. 30.—In a semi-circular weir or opening with closed top, as represented by Fig. 9, the head or radius being ten inches, what is the flow in cubic feet per second?

Cal.—By Table 4 the flow due a head of ten inches is 1.6713 cubic feet.

By Rule 19 there results—

$1.6713 \times 2.1568 = 3.6047$ cubic feet.—Ans.

Ex. 31.—In a circular weir or opening touching the water surface, as at A, Fig. 8, the radius is eight inches; required, the cubic feet flow per second?

Cal. 1st.—By Table 4 the flow due a head of eight inches is .9567 cubic feet.

By Rule 20 we have—

$.9567 \times 5.6566 = 5.4117$ cubic feet.—Ans.

Cal. 2d.—By formula (57): 8 inches = $\frac{2}{3}$ feet.

By Table 5, $(\frac{2}{3})^{\frac{5}{2}} = \frac{5.657}{15.59} = .3629$ nearly $24.2129 \times .616 \times .3629 = 5.4117$ cubic feet.—Ans.

FLOW OF WATER THROUGH PARABOLIC WEIRS.

Fig. 11.

Fig. 12.

Let Figs. 11 and 12 represent parabolic weirs, touching the water surface, Fig. 11, at its apex, A, and Fig. 12 at its inverted base, EF.

Let h, in each weir, as AD or HA, denote the head, and let b denote the base, as BD, DC or EH, FH.

Let c = the coefficient of discharge.

Q = the quantity discharged in cubic feet per second,

and $(2g)^{\frac{1}{2}} = 8.025$ due gravity.

Let x = any part of the head, estimated from A, in Fig. 11.

PROSPECTORS.—This is the season of the year when the prospector, after bising in the mountains for several months, digging in the ground in search of the precious metals, and enduring all manner of hardships and privations, gathers up his prospecting outfit and comes to the city and takes up a winter's residence. We do not mean to say that all prospectors do this, only those whose mines have not been sunk deep enough, and of which the excavations are not sufficient to protect them from the severity of the winter weather. If there is one man more than another who deserves the kind consideration and good will of all classes of our citizens, it is the prospector. There is not a mining camp in America but owes its existence to the men who, leaving the usual haunts of men, their families, friends and civilization, and taking up the weapons of their warfare—the pick, hammer, drill and shovel, and strapping a side of bacon, a sack of flour and a few potatoes to a bony looking horse or mule, he goes away into the mountains and trackless desert, and for months, and sometimes years, he suffers all kinds of hardships, and often, very often, he dies in some lonely spot, the only attendants at his dying bed being the wild game of the hills, a faithful dog and his old horse. Very often, however, the prospector meets with better success, for after being on his trip in the mountains but a short time he returns laden down with pay rock, and rejoices over the discovery of a ledge that in a short time makes its locator rich and results in the building up of a city and the maintenance of thousands of human beings.

SQUIRRELS AS PROSPECTORS.—The Virginia Chronicle says: Bradley, the prospector who discovered the new mining camp in Esmeralda, formerly known as Lake district, but now changed to Hawthorne, gives the following account of how he found the rich gold-bearing vein on which the La Panta and other claims are located through the misrest chances. The La Panta lode is what is known as a "blind ledge," there being no surface croppings to indicate the existence of a mineral bearing vein at the point where it is located.

In passing along the side of the hill Bradley's attention was attracted by a mass of decomposed quartz mingled with dirt that had been scratched out by ground squirrels in digging holes in the side of the hill, which was fairly honeycombed with them. He collected some of the quartz, crushed it in a mortar and horned it out, getting a fine prospect in gold. This led him to search for the vein whence the decomposed quartz had been excavated, which he found by following the squirrel holes, which extended close up to the rim of the vein or gold-bearing ledge, one claim on which has been disposed of for \$35,000. Had it not been for the excavations of the whiskered little rodents, the gold-bearing vein that is now attracting so many prospectors and mining men to Esmeralda might have remained hidden for countless centuries.

ALASKAN MINES.—E. W. Haskett, whom the new administration has displaced as United States District Attorney for Alaska, has arrived in this city. In speaking to a reporter, he expressed himself in many respects pleased with the country, but considers it a land of undeveloped resources. "As for the mines," he said, "it is probable that a large portion of Alaska is one vast mineral deposit. As yet, I suppose, all the mining in Alaska could be included within a mile or so square. I would not advise a man without capital to go to Alaska in the hope of engaging in the mining business. There is gold there, and lots of it, but it requires capital to develop and work it. The mines of the Basin and Treadwell mine have paid immensely during the past year, but it has been done with capital. Prospecting is a very difficult matter, owing to the condition of the ground and the thick timber lands. The placer mining is conducted on the hydraulic plan. You see, the mountains are very high and are capped with glaciers. The miners consequently just hitch onto the melting end of a glacier and find an abundance of hydraulic pressure."

STAY AWAY.—The news that work is about to begin at Panamint is already attracting men in that direction. To one and all we would say, stay away, you are not needed, there is no work for any more men there at present. When the road shall be completed, the force now at work upon it will set to work clearing away the rubbish of the burned mill, and doing other preparatory work. This force will be all that Mr. Fairman will employ for some months to come. Panamint is 50 miles out in the desert beyond Darwin, and 75 miles beyond the railroad. There is no chance for men to find other employment in that region, and therefore all are warned to stay away for the present.—*Inyo Independent.*

SHASTA COUNTY is having a veritable mining, manufacturing and agricultural boom. More people have gone to that county this year than to any three other counties in the northern part of the State. Houses have been built on tens of thousands of acres of unsettled lands. Mining was never carried on so actively before, and never looked so promising as now. The bullion product is large and rapidly increasing. As a result of this, the trade is good, and the towns are growing in wealth and population. Manufactures are springing up and assuming importance.

USEFUL INFORMATION.

A NEW SUBSTANCE FOR MIRRORS.—Is glass to be superseded by "ferrolite" in the manufacture of mirrors? Some months ago a Pittsburgh paper gave in detail the discovery of a new material invented or discovered by Dr. E. Rosenzi, the well-known chemist of that city, and named by him "ferrolite." The new substance had been found to be identical with that from which the obsidian mirrors used in ancient telescopes were composed, and the secret of making which was lost to mankind several hundred years ago. Dr. Rosenzi made and sold several of these mirrors, one of which went to the Imperial Observatory at St. Petersburg, Russia. He felt the greatest confidence that his discovery would in time be utilized in the arts and commerce, but, lacking the necessary capital to bring its manufacture on an adequate scale, allowed the matter to rest quietly. A few months ago, however, he succeeded in interesting a number of leading Pittsburgh and Beaver county capitalists in the matter, and a company has been organized in Rochester, Pa., and a factory building erected and the necessary furnaces, machinery and appliances put in for the manufacture of ferrolite of obsidian mirrors and other articles of use and ornament.

SOLDER FOR GLASS AND PORCELAIN.—A soft alloy which attaches itself so firmly to the surface of glass and porcelain that it can be employed to solder articles that will not bear a high temperature can, as the *Pharmaceutical Record* asserts, be made as follows: Copper dust obtained by precipitation from a solution of the sulphate by means of zinc is put in a cast-iron or porcelain-lined mortar and mixed with strong sulphuric acid, specific gravity 1.85. From 20 to 30 or 36 parts of the dust are taken, according to the hardness desired. To the cake formed of acid and copper there is added, under constant stirring, 70 parts of mercury. When well mixed, the amalgam is carefully rinsed with warm water to remove all the acid, and then set aside to cool. In 10 or 12 hours it is hard enough to scratch tin. If it is to be used now, it is to be heated so hot that when worked over and brayed in a mortar it becomes as soft as wax. In this ductile form it can be spread out on any surface, to which it adheres with great tenacity when it gets cold and hard.

HOW TO KEEP CHESTNUTS SOFT AND SWEET.—The chestnut is not strictly a fruit, but thousands of boys and girls like to eat it in late fall or winter, and many of them do not know how to preserve it so that it shall be pleasant eating in winter. Generally it soon becomes as hard and dry as marble, but this is unnecessary. When first gathered put the nuts in a common bag—not a paper one—and expose them a few days to the sun and air on some roof, wood pile or fence. Stir them over occasionally, so that they do not sweat and mould. They will become a little warty, and when this is the case uniformly and they seem dry, hang them in the cellar—not in any chest or closet up stairs—so that no mouse, squirrel or rat can reach them. If properly cured when placed there they will remain sweet and soft all winter; if not cured they will mould in the cellar, while above the cellar they will become too hard for anybody's teeth.

BRAZING.—A correspondent of the *Blacksmith and Wheelwright* writes in regard to "brazing," as follows: I wish to say a word about brazing. I am not an expert at brazing, but I have had fair success in the method I follow in such work. It is as follows: I get the iron bright at the point where the brazing is to be done. There must be a good clear fire with coal well charred. The pieces are fastened together as closely and firmly as they can be, and then put in the fire so that they can be watched easily. I then take some sheet copper such as turners use, cut it into fine pieces, and lay them on the iron at the place where the brazing is needed. Then fine borax is applied, and the bellows are worked steadily until the copper melts and runs. It is advisable to turn the iron around so as to get the copper into all the cracks. The piece is then taken out of the fire and allowed to cool, which finishes the job.

WHEN A LEATHER BELT has been slightly injured by being wet in any manner, it should be dried as much as possible, and laps that may be started can be fastened by a little cement, the composition of which, as follows, is furnished by the Page Belting Company: Equal proportions of good glue and Prussian gelatine dissolved in water, and cooked in a tin vessel set into a large one containing water. Do not allow the vessel containing the cement to set quite on the bottom. It should be cooked until it is quite thick and ropy; it can then be worked in the places where the laps are started by means of a knife. The belt should then be hammered until dry and a few pegs may be used, which can be obtained from any local shoemaker. Cut the pegs off a little from the surface on the reversed side, and hammer them down on a flat-iron, anvil, or lapstone.

A LARGEST BLOCK OF MARBLE ON RECORD.—Mr. Odell, the efficient superintendent of the quarries of the Vermont Marble Co., at West Rutland, Vt., has the distinction of making the largest raise of stone ever made at one time. A huge mass of marble eight feet in thickness and 54 feet in length, weighing, by actual

measurement, 876 tons, was recently lifted from place by a line of plugs and feathers. The entire mass was lifted from the bed without the slightest injury to the marble, and was afterwards broken up into blocks and lifted to the mills. At this rate, the expense of quarrying marble should fall below 10 cents per foot.

POLISHING POWDER FROM ASHES.—The *Iron Trade Review* gives what is stated to be an original recipe for making from anthracite ashes a polishing powder of much value for polishing machinery. Sift the ashes, fill a pail one-third full of ashes; fill up with water, stir well, with one-quarter of a minute for coarse grade, one-half minute for medium, three-quarters of a minute for fine suitable for fine metals; then pour off into another vessel to settle. When settled pour off the clear water and dry the sediment any way you please, in a bakepan on a stove, but not too quickly. It is, says the writer, the best polishing powder in use, and the cheapest.

SOME THINGS WORTH KNOWING.—To make green blinds that are faded look like new, brush them over with linseed oil. Black ornaments may be mended with shellac. Smoking the joint renders it black. If the brass top of a paraffin lamp has come off, it may be repaired with plaster of Paris wet with a little water, and it will be as strong as ever. Tough meat may be made as tender as any by the addition of a little vinegar to the water when it is put on to boil. Fish may be scaled more easily if dipped for an instant in boiling water, or if they are slightly sprinkled with salt.

A TYPE AND STEREOTYPE SETTING MACHINE.—A machine which is said to enable the operator to set type and stereotype at the same time was experimentally tested in Baltimore a few days ago, and several newspaper men from different parts of the country are reported to have invested in it for its value in book and job work, though doubtful whether it can be made to meet the requirements of a newspaper composing room.

A SUPERIOR BLOTTER.—Blotting paper, saturated with a solution of oxalic acid and dried will not only absorb the ink of a blot, but will remove the blot itself, if the ink does not contain indigo or aniline color. It might be dangerous in removing signatures from important papers, but the trace of this writing will remain, and can be made legible by adding ferrocyanide of potassium or gallic acid.

The decay of stone, either in buildings or monuments, may be arrested by heating and treating with paraffine mixed with a little creosote. A common "paint burner" may be used to heat the stone.

CLEAN AND OIL LEATHER BELTS without taking them off their pulleys. If taken off they will shrink. Then a piece must be put into them and removed again after the belt has run a few days.

GOOD HEALTH.

Hot Water in Dyspepsia.

The internal use of hot water in various ailments, but especially in dyspepsia, is exciting a good deal of interest, both among the people and among physicians. The leading medical journals are also devoting much attention to a favorable discussion of the subject. The *London Lancet* and the *New York Medical Record* recommend its use. A practicing physician gives an extended personal experience of its use in a late number of the last named journal. He was prostrated in 1883 by sunstroke, which brought about a serious disarrangement of the stomach that resulted in the habitual ejection of his food from that organ. After trying various remedies without avail, his attention was attracted to the use of hot water by reading an article in the *London Lancet*. He resolved to try it himself, which he did, with the following result, as described in the *Medical Record*. Before rising in the morning he had his servant bring him a pint of boiling water. This, so hot that he could not touch his lips to it, he drank, drawing it through a tube, during the space of 12 minutes.

His lay in bed one and a half hours longer, and then took his breakfast and retained it on his stomach with no unpleasant feeling. He did the same one and a half hours before dinner and supper, and a half hour before retiring.

This course he continued for several months, using no other fluid whatever. The vomiting was wholly arrested from the very first. For the next nine months he used the hot water less regularly, with occasional return of the vomiting. A subsequent change of climate helped to complete his cure and to do without the water. He since used it in his own practice, with excellent results every time the treatment was persevered in.

RAW POTATOES FOR THE COMPLEXION.—Most women value a clear complexion, if attainable. Helen of Troy is said to have bathed daily in wine and milk to preserve the purity of her silky skin. Cleopatra used various medicated ointments and fragrant cosmetics to enhance her charms. Catherine of Russia habitually washed in strawberry juice; while strange and grim tales are told about the preparation of the

mysterious baths Ninon L'Enclos is supposed to have indulged in. Our fair sex are less luxurious in these days, and we find that ladies who value a transparent white skin—a delicate complexion in which the tint of the rose is softly blended with the snowy hue of the lily—are now being advised by an eminent authority on this art of keeping beautiful forever, to frequently apply the end of a raw potato to the face and neck by gentle rubbing. After rubbing, the face and neck should be washed, and gentle friction is to follow. Ladies are strongly urged to always keep a raw potato on the washstand. One great advantage the potato seems to possess over many other skin beautifiers seems to be its exceeding cheapness, as one potato may be used over and over again, since it is only necessary to remove a little of the outer surface and to pare off a thin slice before applying the freshly cut surface.

What Shall We Drink?

Of all stomach questions this is the most difficult to answer. If coffee and other beverages were disagreeable, and we drank them as a duty, it would all be easy. Duty is weak, appetite strong. If your teeth are good, chew your food till it is ready for deglutition and digestion. Without this you miss the full pleasure of eating. To bite a piece of bread in two or more pieces and wash it down with coffee or tea is to cheat the palate.

You need considerable water in the system to run the machines. This may be taken on rising and on going to bed. If within a mile or two of a spring make it a visit early in the morning, and take one or more draughts of fresh water charged with electricity from the earth. To boil water is to lessen its physiological value. There is something magical in the influence of water fresh from a spring, drank on rising in the morning. Cold water morning and night is so stimulating to the alimentary canal that it relieves constipation.

Milk is a bad drink for students. Those who have studied the laws of digestion in the light of Beaumont's experiments know that a quantity of milk in the stomach must interfere with the digestion of solid food. Milk, even when taken with simple bread, will not leave the brain as clear as will dry food with abundant mastication.

Tea and coffee injure the brain of the student. The human brain no more needs the stimulous or narcotism of tea and coffee than does the brain of a deer or race-horse.

Alcoholic drinks are poisons. We drop a little into a man's eye. It reddens and irritates it. The eye is not scratched, it is poisoned.

A living man with an opening through his side into his stomach presents himself for experiment. It is the famous case of St. Martin. Gazing through that strange opening we see, when alcohol is introduced, the same poisoning as in the eye. So strong was this Frischman's stomach that on going to bed at night he could gorge himself with the most indigestible food, and the lining coat of his stomach would show no irritation the next morning. But when he was given a glass of pure French wine, the lining the next morning showed a distinct irritation. After a glass of whisky the veins were very much swollen, and the irritation continued several hours.

And now we study the stomachs of drinking men after death. The moderate drinkers show a stomach resembling St. Martin's after the wine. The free drinkers discover a worse lining. Hard drinkers show a stomach dotted with dark ulcers. The stomach of the poor wretch who shrieks out his life in delirium tremens is a putrid-looking mass riddled with black destruction.—*Dio Lewis' "Nuggets."*

THE HYPODERMIC NEEDLE.—Frightful accounts of the opium evil appear from time to time in the newspapers, and it is probable that the half has not been told. A writer in a St. Louis paper tells of a bright and beautiful woman who buys \$20 worth of opium at a time. When her supply of the drug is out she wakes up in the night in the utmost agony and bites her arms until they are torn and bleeding.

A celebrated actress gets fairly wild about 2 o'clock every afternoon, and she makes an excuse and gets by herself for a few minutes. When she returns she is a changed woman, for a short time pleasant and talkative, and then she begins to drift into a semi-unconscious state. Her eyes shine and look at you, through you and beyond you. Then she will start, beat a tattoo with her hand, stir up her bang, brace up for a few minutes and float away again. This continues for hours. At a big dinner she will drift away over her plate, rouse herself, take a fork and separate some portion of her food, have another relapse, and so on through a long dinner without eating a mouthful. Sometimes she suspends her awful habit and adopts as a substitute whisky, tobacco and other things; but she always returns to the hypodermic needle.

A NEW CLOTH FOR RHEUMATISM TO WEAR.—As for the wool question, it is probable that vegetable fabrics are even better clothing than animal, and as a fact wool of the most valuable kind for hygienic purposes—a specific almost for rheumatism—is now being made largely from the leaves of the fir. I, myself, am wearing that manufactured by Laivits, from pinaster, or black pine, and find it in every way admirable, whether for under or over clothing. The *Lancet* pronounces it far superior to animal wool.—*Anna Kingsford.*

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

VARIOUS MINES.—Amador *Sentinel*, Oct. 28: Three men are engaged in retimbering the Tripp & Littlefield mine. An arastra is being put up on the Cleveland mine, near the Big Bar bridge. Work is progressing at the Kennedy mine. The lumber is now being delivered. The Pacific mine, Plymouth, is closed down while the shaft is being retimbered. The men who have bonded the Mahoney mine of Sutter Creek, are expected up every night. Tom Read and Geo. Busb of Plymouth, have been in town for a couple of days. The Shugert mill was running its full twenty stamps last night being supplied from Horne's ditch, the lumber supply in which is reported as increasing. Louis Isola is said to be developing a fine mining property on John Belluomini's ranch. The shaft is down forty feet, with a drift of forty feet, in which is a four-foot ledge showing gold very freely. We were told the other day that some Eastern mining men would soon visit this county looking for a mining investment. They are said to be men of sand, having sunk in unprofitable ventures in Arizona and Colorado two or three million dollars. Amador is a good county in which to get even and we trust they will find something here to suit their taste.

SOUTH SPRING HILL.—*Ledger*, Oct. 31: The recent clean-up of this mill for a run of 15 days with only 10 stamps, crushing 16 to 18 tons per day, realized nearly \$7000 in free gold, besides sulphurets, which will give \$800 more. This is the handsomest yield yet made by this splendid mine, being an average of over \$25 per ton. The mine is looking better than ever, the ore body in places being over thirty feet wide, and of high grade. At the mill, the work of putting in ten additional stamps is almost completed, but the woodwork of the original ten stamps will have to be renewed. One of Knight's improved wheels is also to take the place of the old one. The Hendy concentrators have been taken out, and two Frue and two Triumph concentrators have been put in opposite the ten new stamps. This is for test purposes, and whichever make proves the most efficient will be adopted for the other batteries—making eight concentrators all told. The mill is likely to be idle until the rains increase the water supply, as it is not fitted to run by steam.

MISCELLANEOUS.—The Mammoth mill was brought to a standstill last week on account of a failure of the water supply. There is nothing doing at the mill or mine. At the big tunnel at Middle Bar, the work of putting up the new and more powerful air compressor is under full headway. It will take two or three weeks to get it in running order. The Bunker Hill mill was compelled to close last Monday, on account of a scarcity of water. It is supplied with steam fixings, but even battery water cannot be had, the Keystone requiring the whole of the supply. It will probably have to take to steam in a few days, and then there will be battery water for the Bunker Hill. A rich strike is reported at the New York mine, 5½ miles south-west of Jackson. At a depth of 120 feet a body of quartz has been discovered, which shows plentifully in free gold and sulphurets. We have not heard the extent of the ledge. W. C. Anderson has stuck to this claim persistently for several years, and he deserves the good fortune which appears to be dawning upon him.

SUTTER CREEK.—F. B. Latham, Secretary of the Consolidated Amador Mining Co., has been here for several days in company with a gentleman named Gillette, the largest English stockholder. As to what will be done with the mine, nothing definite is known as yet, but in all probability there will be an entire change of program. The machinery will most likely be put back on the old shaft, and the water taken out to a certain depth, which proposition is universally approved here, as most likely to place the mine once more on a prosperous basis than any steps which have been taken since the old shaft was abandoned. Since the closing of the Mahoney, one of the engineers and one or two other men have been kept on to keep things straight around hoisting works and mill. They have devoted a portion of their time to prospecting, and recently they discovered a ledge north of the hoisting works, which has opened out into an ore body of considerable dimensions. A good track has been laid, and about 200 tons of rock is now on the dump. This ledge is favorably located, so that a few men can easily keep the 40-stamp mill going, and it is believed that the rock will pay a fair profit. The Canal Co. have a number of men at work fixing flumes, etc., and placing the canal in condition to withstand the winter's storms. The Amador reduction works resumed operations this week, after six weeks' idleness.

Butte.

BUTTE CREEK.—*Cor. Record*, Oct. 31: If Butte Creek was five hundred miles from where it now is, with its present prospects, instead of having the number of miners it now has, would have hundreds of men driving drifts into the hills, and plenty of coin to back them. The trouble is it is too near home, and as often said too old a mining camp. The day is not far distant when the people of Butte county will be astonished at the wealth upon Butte Creek. Drift diggings are what we want; this kind of mining will pay. Above this place much gold is being taken out. The Indian Spring, Pershacker, Cole, Merideth, McIntyre and Foley claims are all of first-class paying mines. John Nicoll is opening up a claim just above Helltown, and from all indications it will be a paying piece of property from the start. C. Smith has started a drift near the lava on the west side of the creek; success to him. I am satisfied he will strike pay gravel in running fifty feet. All are sanguine of there being good pay under the mountain. Bowman is on the east side two hundred and fifty feet, and has found paying gravel, it pays him three dollars per day, and every appearance of being a "stayer." Ben Gale and Harry Moore are driving the Foley drift back into the hill with encouraging prospects. C. Hintz & Co. have started a drift just below the bridge, intending to mine out the flat, which is richly charged with gold their energy and perseverance will insure them success. Moss & Co. are driving ahead, doing an ex-

tensive business by way of tearing down the hills. The Frisker claim was recently sold (so we hear) for fifteen thousand, and the company will soon be at work taking out the root of all evil.

Calaveras.

GOLD.—Mountain *Echo*, Oct. 30: We learn from good authority, that Hugh Duffy and Edward Purdy lately uncovered an immensely rich deposit of gold in their mine on Dead Horse hill, near this town. It is said that they have already taken out quite a large sum of money. The quartz mine owned by John Graham and Joe Whittle, situated near Albany Flat, is yielding handsomely; in fact, it is considered one of the richest mines in this section. Since the water has been turned out of the ditch, a good deal of prospecting is being done, and new mines are being developed.

FROM MURPHY'S.—The Canon mine bonded by the Kelly brothers to Mr. Canon for \$10,000, is in a prosperous way to develop into a valuable piece of property. There are now six men at work on this mine, and lumber will be hauled this week for the construction of suitable buildings for the accommodation of the workmen. The new shaft is now down near 20 feet, good progress having been made since the commencement. The vein is of good width, averaging over two feet, free milling, and the bright shining metal plentifully sprinkled through it. John Boyle, who is an experienced miner, and an expert in mining matters, is foreman of the mine.

MILL.—Calaveras *Chronicle*, Oct. 31: We learn that Mr. Kervin is putting up a 10-stamp mill on the Fine Gold mine. It will be run by water power and no doubt it will pay from the start as there is a great abundance of \$75-ore exposed in the mine. Just as we go to press we learn that the deal has been made on the Cook mine, the price paid being \$50,000. The purchasers are W. A. Nevills, Col. J. M. Morehead and Mr. Henry Janin of San Francisco. The acquisition of this valuable property by such thorough-going mining men indicates the building up of a lively camp at Greville in short order. We hear that a fine prospect has been struck in Fred Greve's ranch by Dr. Wright and two Colorado prospectors. Quite a considerable amount of prospecting is going on at West Point, and some rich ore is being produced. A. L. Redstone & Co. are getting their big stamp mill up on the Champion mine, belonging to Geo. Simpson & Co. It will be ready for business in about two weeks, and as its capacity is as much as 60 tons per day big shipments of gold must follow, especially as the Champion mine contains good quartz.

Marin.

ANOTHER GOLD MINE.—Marin *Co. Journal*, Oct. 30: The glories of the Bismuth mine on Mr. Rose's, and the adjoining property, have paled during the week before some astonishing developments of gold and silver, which have been found in the same rock at a little greater depth. The discovery was made by observing flakes of free gold in the rock with the naked eye. This led to making some assays, one of which showed gold of the astonishing richness of fully \$2000 to the ton. Mr. Rose is pushing his prospect with energy born of great hope, and we trust he will be better awarded than our former discoverers of precious metals.

Mono.

MONO'S NEW DEVELOPMENT.—Bodie *Free Press*, Oct. 30: Superintendent Kelly of the Bodie and Mono mines this morning escorted a couple of cage-loads of Bodieites down the Lent shaft and through the Mono, the special object of course being to take observations of the new find. The sight-seers were landed at the 550 station and passed through the south drift into Mono ground. Descending a winze 100 feet the party explored the new bonanza. In the drift the showing of the bunches of pay rock, with stringers of quartz tally exactly with John Kelly's published reports. He has not stated, however, the fact that a very apparent and comparatively smooth foot-wall well defines the ledge. On the east side there is no "wall," so to speak, but characteristic indications of another ledge or ledges lying alongside. In the drift, some 75 feet in length, stringers of rich ore reach along the top and bottom, concentrating at the end. A winze about six feet deep now being sunk discloses the apex of a chimney of ore, widening to the southward and at the bottom. At the bottom the ore body is 38 inches in width. The rock is bright with native silver, and shows flecks of gold. The ledge is easily picked out in a soft and "motherly" formation, in virgin ground. It would require the most scientific "rock sharp" to detect the difference, if any there be, between the specimens which were readily broken out with the point of a candlestick and those from the old Burning Moscow and the Mexican of the Comstock in early days. The strike, at its comparatively great depth, in unexplored ground, remarkable richness, and all, is the most important event Bodie has experienced in some years. These are facts and may be taken for what they are worth, however affecting Pine street.

Nevada.

GOLD PRODUCERS.—Foothill *Tidings*, Oct. 31: The Crown Point is still looking well, the mill being kept running night and day on pay ore. Mr. Gauthier intends soon to run another level below the present one, for the purpose of ascertaining the extent of the vein. Mr. Hendy is now engaged in the Crown Point mill putting up two Triumph concentrators, which will be running in a few days. The North Star is also looking well and is improving in appearance. The mill will soon be enlarged in order to accommodate the ore. The North Banner crosscut is near the ledge, which will be cut in a few days. The several stringers run through by miners proved to be very rich. Work is steadily going on in the Boston (Granite Hill), located near the Larimer mill on Wolf creek. The shaft is down over 200 feet, with drifts running from it. A clean-up from a crushing of 40 loads just made yielded between \$40 and \$50 per load, the exact figures not yet having been made. The Phoenix continues to look well and the owners have the greatest confidence that they have a rich mine. Thursday some more rich ore was hoisted. The Green Mountain will soon have a clean-up.

NORTH BANNER MINE.—Grass Valley *Union*, Oct. 31: Prospecting operations in the North Banner Con. Tunnel Company have been going on actively through the season, and a crosscut from the tunnel is now near the ledge, which is expected to be cut into any day. Several stringers putting down toward the ledge have been cut lately, all of them

showing gold. The present tunnel is lower than the old one, and will have a considerable extent of backs above it. The rock from the mine has always been of fair quality, and the company having its own mill and water power can do the milling cheaply. The North Banner always has been a good prospect, and the probability of there soon being a large body of ore at command gives a promise of future favorable results.

A GOOD OUTLOOK.—North San Juan *Times*, Oct. 31: Several months ago while Martin, Waters & Co. were hydraulicizing a small deposit of gravel, at their quartz claim on Canada Hill, near the Charonnat mine, they uncovered a fine-looking ledge. About the time of the discovery Deputy U. S. Marshal Robinson served an injunction on them, whereupon they quit washing and began running a drain tunnel. This tunnel is now in 100 feet, and when they get 70 or 80 feet farther they will have 200 feet of back. They have taken out about 100 tons of excellent ore in running the tunnel. Only six or seven men are working at present, but as soon as the tunnel is completed quite a force will be put on. The four-stamp mill is not running, the owners bending all their energies to the thorough opening of the claim, which is one of the most promising of the many good properties in this section. The 24 Chinamen who purchased, some time ago, the Sweetland Creek Placer mine at Buckeye Hill, this township, paid their last installment on Wednesday the 28th, and received their deed for the same. This placer mine has a history, and an unlucky one too. Many years ago it was sold by General O. Evans, Thomas Cloake, Peter Purcell, the late John S. Stidger and others, to an English Company for the sum of \$200,000. Subsequently it was sold by said company to George E. Yates and George D. McLean for the sum of \$25,000, who sold it to the late owners for \$5000, and they in turn sold it to the Chinamen for \$8400. The English Company realized, it is said, over \$500,000 in dividends from this mine, and supposing it to be worked out, sold it to Yates & McLean for \$25,000. They realized about \$700,000 from it and sold it cheap, believing it to be entirely worked out. The Chinamen have made a rich thing out of it, and have plenty of rich paying ground left.

MORE RICH QUARTZ.—Rich strikes of quartz is the order of the day in the Grass Valley district at the present time. Yesterday some rock was taken up from below the floor of the 200 level of the Phoenix mine 30 feet from the shaft, which was very rich in free gold, gold-bearing sulphurets and galena. Several boxes of this character of quartz was taken out during the forenoon, and was brought to the office, Coleman & Glasson's store, where it was examined by many persons, and the universal expression was that beside the fact of the presence of gold the quartz itself was of a quality to give encouragement for the future of the mine. The ledge at the point from which this rock was taken out was 12 inches in width, but in the shaft below this level the ledge is showing between one and two feet in thickness. When the shaft is sunk to the 300 level a new drift will be run under where the rich rock was taken out with the expectation that the ledge will yield fine milling rock. The value of the rock taken out yesterday is believed to be nearly \$1000. The Phoenix is an old mine, which has lain idle for a long time, but upon which work was resumed a few months ago by erecting the necessary hoisting and pumping works. The old workings were only put down to the depth of 200 feet, when work was suspended after only limited development had been made. If the old company had prospected carefully they might have come upon good quartz, but it has remained for the present company to make the discovery, and there is now every prospect that the company is going to open a good paying mine.

GOOD FOR THE PEABODY MINE.—The Peabody mine is now being operated under lease by a company of practical miners, who have, since commencing work been extending the second level north, which is 183 feet on the incline. The theory has been that in that direction the pay rock would be found, and this has apparently been demonstrated within the last few days by the coming in of good quartz which shows well in free gold.

Placer.

OPHIR MINES.—Placer *Herald*, Oct. 31: There is, perhaps, hardly a section of California so thoroughly ribbed with quartz veins as the country in and around Ophir, in this county. Many of these ledges have been worked more or less, and many of those worked have, at times, paid. While, for several years back but few mines have been operated, those few have been run by experienced miners on an economical basis, and their success is convincing proof that for those who wish to follow their example the Ophir district offers flattering inducements. Prompted by this belief, many owners and prospectors have recently resumed operations, and a general stimulus has been given to the whole surrounding country, which by spring promises to develop into a regular boom. Mr. W. A. Plantz is just finishing a 10-stamp mill and new hoisting works on what is known as the old Hatbaway ledge. This is a well defined lead running through the country south of Ophir, which has yielded good ore wherever prospected. The Kirkland, the Butts and the Adams mine are all on this same lead. P. Hanson is opening up the old Jamison ledge, close to the town of Ophir. He has put up a wheel for hoisting and pumping, and will be ready for active operations as soon as the water is turned into the ditch again. He will crush his ore in the Pugh mill, near by, in which he is an owner. Shurtliff & Shor have a force at work on the original St. Patrick cleaning out the old shaft and opening the mine again. Harsh & Jacobson are working a lead on the Jaroldson ranch and are taking out ore. This ledge was prospected more or less some years ago and the rock then taken out was of a high grade. The Kaiser boys are sinking on the east extension of the Boulder and are taking out rich rock. Samuel Kaiser and the Lozano boys are working on the old St. Lawrence, below Ophir, and are highly encouraged. On the Gold Blossom, where there are steam hoisting works and a good mill, work has again been resumed under the superintendency of Mr. M. B. Burlingame. A new shaft is being sunk, now about 100 feet deep, and some good rock is coming out. The mill is idle at present for want of water. The Morning Star, owned by the Peardon and Hawkins boys, still maintains its reputation as one of the best quartz mines in the district. A new Friedenberg wheel is being put up in the mill and five more stamps added, and pending this work of

course they are crushing no rock. Their last crushing from shaft No. 3, which is down about 150 feet, went about \$20 to the ton. Shaft No. 1 is down about 400 feet, and at that depth the ledge is on an average 3½ feet wide, and the rock now out and on the dump, nearly 200 tons, is estimated to go about \$30 to the ton. Lou and Chas. Kittler are working on an extension of the St. Lawrence. They are down about 75 feet, have a good ledge and some pay ore, and are much encouraged. Ross Bradbury and Chas. Carter are sinking on a ledge close to Mrs. Kittler's on St. Patrick mill site. They are down about 45 feet. At the Boulder, which has lain idle for some years for the want of sufficient power to keep out the water, a fine and substantial new building is about completed, designed to cover the pumping and hoisting machinery, which is about to be put in place. Samuel Howe, an old California miner, is in charge of the work. A Pelton water wheel will run the hoisting works and pump. A new mill on this mine in the near future is one of the probabilities.

Sierra.

MORE GOOD QUARTZ.—*Mt. Messenger*, Oct. 31: We learn that a ledge of rich quartz has been discovered on the ridge between Butcher Ranch and Gold Valley by Wm. Meserve, Jo Logarmisno and Mr. Myer. As we understand, the ledge was a blind one and was sunk for and found simultaneously by two parties, viz., Meserve and Logarmisno and Myer, at a depth of only a few feet. Neither party seems to have known that the other was prospecting in that vicinity until they met while running out their lines.

PUMP STARTED.—The pump at the Extension shaft was started last Tuesday, and at last accounts was working smoothly. Running at the rate of 10 strokes a minute, the pump throws about 30 inches of water, which will be more than the necessities of the mine require with the present working force—about 70 men. The job of putting the pump in place, which is the work of Mr. Collins, is said to be first-class in every respect, the pump working so easily and smoothly that a person standing near it would not know it was running did he not see it move. George Parent has sold the Tippecanoe mine, recently purchased from the Extension Company, to a Chinese company which has been working the ground for the past year. The heathens had a good thing—working ground that belonged to other parties. The new pump at the Plocene shaft, belonging to the Extension Company, began working Monday, when, with an increased force, breasting was resumed at the mine.

Shasta.

WHISKYTOWN.—*Cor. Shasta Courier*, Oct. 31: Preparations are being made to build a quartz mill near this place for the purpose of crushing rock from the old Phoenix mine which has again been placed in working order. J. S. Strode has moved his cannon ball mill from Dog Gulch to a new find which he has made on Whisky creek about one mile from here. Several parties have visited the Mad Ox mine lately with a view of leasing that property. Work is progressing nicely on the Mad Mule mine under the superintendency of F. M. Stocking. Report reached here today that a rich quartz lead has been discovered on Deadwood Gulch, about one mile from the Mad Ox mill, by A. L. Ferguson, an old "forty-niner," who mined here in early days. He came back to his old claim thinking there was a hidden treasure there. The name of the Postoffice here has been changed and is now Stella.

SILVER.—Shasta county *Democrat*, Oct. 31: Two silver bricks weighing 165 pounds were shipped from Copper City last week. Tom Green came down Monday with another chunk of amalgam and yesterday returned with a load of lumber. Two tons of ore from the Altoona quicksilver mine in Trinity county were shipped last week to San Francisco to be worked. Last week Haskell, Teneyck & Co. shipped to San Francisco two tons of their best ore from their mine on Slickrock to be milled as a working test. We hear it stated that the Iron Mountain Mining Company has bonded two more mines adjoining the Lost Confidence from Camden, Magee & Co. for \$75,000 each. It is thought that the Iron Mountain Mining Company will have its mill up by the middle of next month. Just now that camp is the busiest and liveliest in the county. Developments are being pushed ahead night and day. Dan O'Neal started up his mill yesterday on custom rock from the second extension of the Florida, as an accommodation to Forbes & Co. They will mill about 30 tons of high-grade ore. Dan went to Red Bluff yesterday to examine a 20-horse power engine he expects to purchase. W. W. Morely of Oak Run was in town last Saturday and showed some very fine ore he lately struck in his mine near Furnaceville. The ore assays way up, is heavily sulphureted and also pans out in free gold. Friend Morely evidently has a splendid prospect for a rich mine, and is developing it as fast as his means will allow. An old gentleman by the name of Kemp last Thursday struck a very rich gold quartz prospect east of Shasta on the Iron Mountain road. The vein is about 20 inches wide and carries a red ochre seam that is very rich; the rock is also literally speckled with free gold.

Tuolumne.

RICH.—Tuolumne *Independent*, Oct. 31: We learn that Mr. Rapp and the McArdle brothers, of Tuttletown, have taken out some \$8000 during the past month on the Rapp quartz mine above Robinson's ferry. For several days \$1000 per day was obtained. The rich spot was discovered in a singular manner. Near the cabin was a large boulder which Mr. Rapp wished removed. A blast was put in and fired as the parties went to dinner. On their return, in removing the rock, they discovered it was full of gold.

POCKET.—It is reported that Mr. Joseph Whitde has just struck another pocket in his claim near Albany Flat, from which he has taken the large sum of \$35,000. He is an uncle of Mrs. Ed. Henderson, of Sonora.

Trinity.

NEW RIVER.—Trinity *Journal*, Oct. 31: A friend writes us that there are about 200 men in the New River mining district, and that an abundance of food for winter has been packed in. Most of the miners now there will remain all winter. There are three arastras running, one at the Hard Tack, one at the Mountain Boomer and another at the Tough Nut. The Buckeye Co. has recently made an important and rich discovery. The Ridgeway Co. has cleaned up, and while the amount realized is

not made public, enough is known of the richness of the mine to satisfy an observer that it was no small sum. The Uncle Sam has commenced crushing and others will follow as soon as water becomes plentiful.

NEVADA.

Washoe District.

HALE & NORCROSS.—*Enterprise*, Oct. 28: On the 3000 level crosscut No. 3, about 40 feet south of the deep winze, remains just as it was at last report. It is in 15 feet, with its laces all in excellent ore, or as Archie Norland expresses it, "as fine a face of ore as ever was seen on the Comstock." This has been held in abeyance in order to give the other crosscuts a better chance for driving ahead, and in order that heavy stockholders might have an opportunity of seeing what they had there in place before proceeding further. It is proposed, however, to go ahead with this drift directly, commencing about to-morrow or next day. This will cut directly into the heart of the best portion of the ore vein on this level, and very decisively determine its true bullion merits. Crosscut No. 2, farther south, 90 feet from the Chollar line, is in 85 feet, and shows strongly mineralized quartz, with streaks and spots of ore, improving with further advancement. On the 3000 level the crosscut west, near the face of the main lateral drift, was advanced to the distance of 30 feet from the main drift, and last Saturday night tapped a strong flow or seepage of boiling water, amounting to several inches. Work was stopped, and since then the water has been gradually subsiding and draining out. It will be sufficiently drained to allow of work being resumed there shortly. This flow of water is considered good evidence of an ore body lying to the westward.

CHOLLAR.—The principal work on the 3000 level is confined to the branch lateral drift southward from the Combination west drift. This drift has been advanced to the distance of 187 feet, passing in a direction west of south diagonally across the main vein to the west side of the same. Its direction is now changed to due south and it is proposed to run it through to the north line of the Potosi mine, a distance of 320 feet, unless prevented by some unexpected strike of hot water or other adverse circumstance. This drift is now being run in the wall rock along the west side of the vein, the material being dry and working well. The explorations will eventually be carried further west, penetrating the diorite or west country rock of Mount Davidson. Where this drift passed through the ledge it was found to be over 60 feet in width, all solid quartz, and carrying more or less of the precious metals, but not concentrated into a paying ore body at any point. The ore vein certainly does show great strength, if not richness, in that direction.

YELLOW JACKET.—The old upper workings, from the 1300 level up, continue their daily output of 170 tons, keeping the Brunswick mill well supplied and steadily running. The drift north on the 1700 level from the Crown Point through the Kentuck is making good progress, and bids fair for making important developments at that depth. Considerable prospecting work is also conducted in the old upper workings, at the same time the ore extraction goes ahead. There is a perfect wilderness of low-grade ore in this mine, and occasional streaks of higher grade are met with.

OPHIR.—On the 400 level the main drift west from the Mexican shaft continues passing through the same character of vein matter as last week with no improvement apparent. Upraising will soon be commenced to stope out the good ore known to exist above this level as high as the 250 level, and perhaps higher. A drift has been started south from this main west drift, at a favorable point in the ore vein, to explore for good ore thought to lie in that direction.

BEST AND BELCHER.—The crosscut west on the 1000 level, 100 feet south of the old Consolidated Virginia south lode was advanced only a distance of six feet, making a total length of 372 feet. Work in the face was then suspended and a drift south started at a point in the crosscut 250 feet west from the main lateral drift. This new lateral drift south is being run to explore a favorable point showing strongly mineralized quartz, and has been run into it a distance of 48 feet.

ALTA.—Excellent progress has been made during the past week in the west drift on the 700 level, the rock working very favorably. Only about 50 feet remains to carry this drift through to the ore body it is being driven for.

CROWN POINT.—Owing to the breaking of the main spur wheel and pinion at the hoisting works, all work in both this mine and the Belcher has been suspended for a week.

CON. CALIFORNIA AND VIRGINIA.—From the 1750 level about 100 tons per day of ore is being extracted on company account, average assays being about \$18 per ton. A few tons are extracted in the Jones lease section, above the 1300 level, opening out the old workings and preparing for extensive ore extraction during the coming winter, or when the mills on Carson river are again able to run.

MONTE CRISTO.—The new shaft is down 150 feet in dry, hard blasting rock. Further sinking is suspended, and a drift started for the ledge, which is in thirty feet. Are engaged at present in the extraction of ore from the mine through the old shaft for the mill, the supply on hand having run short. Will resume work at the new shaft shortly.

KENTUCK.—The extraction of low-grade ore from the old upper workings continues to progress with the utmost regularity, and is hauled by teams to the Rock Point mill on Carson river for reduction. That famous ore demolisher never stops.

UNION CONSOLIDATED.—The crosscut east on the 500 level, 100 feet from the Sierra Nevada line, was advanced 45 feet last week, making a total distance of about 70 feet. It is running in very promising vein matter, consisting of decomposed quartz, clay, etc.

GOULD AND CURRY.—On the 1000 level the crosscut west has been extended 50 feet during the week, making a total distance of 606 feet. The material encountered at present is soft vein porphyry, with an occasional streak of quartz and clay.

MEXICAN.—On the 500 level the middle crosscut east was extended nearly 70 feet during the week, the formation consisting of soft vein porphyry and heavy clay, with streaks of decomposed quartz.

SIERRA NEVADA.—On the 550 level the north lateral drift from the west crosscut has been extended 65 feet during the week, making a total distance of 95 feet. It is in quartz principally, considerably mineralized, carrying good streaks and bunches of ore. Some little water is met with, and the formation of a character favorable to the finding of an ore body.

Columbia District.

MT. DIABLO.—*True Fissure*, Oct. 30: The incline has been sunk 19 feet during the week and a shaft will at once be cut out for the seventh level. The east drift on the sixth level is in 169 feet, and the west drift on the same level is 415 feet in length. The winze from the east drift on the fourth level is down 41 feet and shows ledge matter with spots of good ore. The raise from the intermediate, between the fourth and fifth levels, shows six inches of 550 ore, and has nearly connected with the fourth level. The raise from the east drift on the second level is up 34 feet and shows a small amount of ore.

Eureka District.

ORE SHIPMENTS.—*Eureka Sentinel*, Oct. 31: During the week ending yesterday ore shipments from the mines of this district were made in the two reduction works in town as follows: To the Richmond—Wide West mine, 9 tons; Home Ticket, 23; Scorpion, 3; Morning Star, 31; Dunderberg, 10; Lone Pine, 5; Geddes and Bertrand, 30; Rescue, 5; San Jose, 5; Macon City, 7; Hamburg, 17; and White Pine 4. To the Eureka Con.—California, 25 tons; Lizzie J., 9; Revellie, 4½; Eureka Tunnel, 1; Dougherty, 1; Summit, 10½, and Alexandria 9.

Moss District.

RICH ROCK.—*Walker Lake Bulletin*, Oct. 28: While everybody is looking for gold and expecting to find a rich mine, Joshua Moss has kept along at his work and, although making no noise, has discovered another ore body in the Montreal mine. The rock now in sight is as rich, if not richer, than any that has been found in this section, and the next stupider will be for the Gillis range and Moss district.

Pahranaagat District.

BULLION.—*Pioche Record*, Oct. 28: Eugene Howell shipped up another bar from Pahranaagat; value, \$1,241.41, 954 fine; results from 15 tons of ore, showing extraction of \$82 for every ton worked. He has thus made a thorough test on 34½ tons of ore from the new find, having made two shipments. In total \$2,542, taking out in wet crushing on this heretofore considered base ore from 80 to 87 per cent of assay value, or \$72.10 for every ton. This test fully demonstrates with systematical working and economical management that the mines in Pahranaagat still possess merit, and when handled on a proper basis can be made pay.

Sweetwater District.

A RICH MINE.—*Eureka Sentinel*, Oct. 31: From a reliable source it is learned that the Frying Pan mine in Sweetwater District, this State, is the richest ever discovered in that section of country. It is said that \$62,000 was offered for the mine, but the owners refused to sell for that price.

ARIZONA.

GOOD ORE.—*Prescott Courier*, Oct. 30: It is claimed that Bullwhacker ore will mill between \$150 and \$200 per ton. The ledge is a fine one; location about three miles from Prescott. Miners say Gov. Tritle has a fortune in sight in the Blue Dick. Mr. Ross, just from Turkey creek, reports progress in taking out ore there. Jacob Henkle and James Daly report very little doing in Centennial district, Yuma county. Jas. Vanderberg has taken seven tons of rich silver ore to the Kingman sampler.

COPPER. we regret to have to say, does not cut a big figure in the metal market. This is bad for Arizona, which has a great many fine mines. As the United Verde mines of this county yield silver, as well as copper, the construction of a railroad into this section will enable their owners to work them with profit. There are besides the United Verde, many fine copper mines in Arizona, notably the Old Dominion, Copper Queen, Lawlor Bros., which are more or less affected by the glut in the market, which, central authorities say, is liable to cause a suspension of copper mining even in Chili.

THE GILA RIVER GOLD DISCOVERIES.—*Tucson Citizen*, Oct. 28: Matt Flynn returned a few days ago from a visit to the new gold discoveries on the Gila near the mouth of the San Pedro, and brings additional information respecting the mines and their developments. The mines are located about two miles from the Gila river, where plenty of water exists at all seasons, and wood abounds in great quantity, the locality being about 64 miles from Tucson by the traveled wagon road. The ore was at first believed to contain only gold, but from recent assays, giving a general average of the ore in several of the claims, they yield about 15 ounces of silver to \$33 in gold, which, counting silver at \$1 per ounce, gives an average of \$48 per ton. The ledge, upon which nearly all the claims are located, is strong and easily traced for a long distance, and the croppings evidence their permanency. The oldest claim is the Sitting Bull, owned by John T. Bates.

COLORADO.

RUNNING.—*Idaho Springs Gazette*, Oct. 28: All the batteries of the Sunshine mill are running on Clarissa ore. As the ore is assorted, it runs well. We saw some handsome ore that has been encountered in the shaft of the Mattie mine in sinking, all of which betokens a pocket of rich ore. On the U. P. R. mine, on Fall river, the drifts are chock full of ore. The mill has been idle, on account of not being able to get teams to haul ore, the road being rather steep and there being a scarcity of teams. The timbers are now being delivered for the dam of the Plutus Company. Work will shortly commence and be pushed to completion. The water power will be utilized to run large air compressors, which will furnish power to run the air drills, hoisting and pumping machinery, thus doing away with steam power and making a large annual saving for fuel and boiler attendance. The time will come when all the machinery of the mines on the creek will be run by compressed air.

DAKOTA.

A BUSY GOLD CAMP.—*Times*, Oct. 28: Within

a radius of five miles of Deadwood, Dakota, there are over 1000 heavy stamps dropping on the low-grade gold ores. There are three 120-stamp mills, one 100-stamp, three 80-stamp, three 60-stamp, two 40-stamp, and 16 20-stamp mills running all day (and the larger one nights) crushing the gold-bearing quartz with their 750-pound stamps. The ore averages about \$6.35 per ton. A new 200-stamp mill is just erected three miles from Deadwood. On such low-grade ore the profitable business is with large mills. The various mines produce annually \$5,000,000, and the mines and mills distribute in payments to their employees over \$150,000 each month. One mine (the Homestake) has, after its first year of operations, paid steady dividends, now aggregating \$2,736,509. Several other mines have each paid to their shareholders upwards of a million in six years and dividends continue as regular as the quarter comes. The mills are kept busy; some are custom mills and have proved profitable investments. All go to make a mining and milling business steady and profitable the year round.

MONTANA.

BANNACK BONANZAS.—*Inter-Mountain*, Oct. 24: We learn from Dr. J. S. Meade, now visiting Butte and one of the owners of the Polaris mine, that they have a showing of five feet of good ore at a depth of 100 feet from the surface in their new shaft. Returns from the last three shipments of ore to Omaha netted \$1692 50. A good hoist and buildings have been placed on the mine. Mr. Connor is pushing development on the Odell property. The Mono mine is to be worked this winter by its owners Messrs. Steel & Mason. Wm. Perkins shipped eight tons of high-grade ore from Elk Horn district this week. The Elk Horn district ores and formation are similar to Butte. Mr. Lancy and Frank Williams are cleaning up good pay from their Gulch mine below Bannack. M. S. Herr is shipping considerable of good ore from the Charter Oak mine. L. C. Fyhrer has a continuous streak of good ore in the Bismarck lode. Phil Shannon expects soon to cut in a rich lode with a long tunnel. The Blue Wing property is now being worked by its owners, Messrs. Gallagher and O'Leary. Mr. Charles Beam foreman.

SWEET GRASS NEWS.—*River Press*, Oct. 25: Joe Supernaut, Fred Derwent, Billy Hagen and three or four others arrived in the city Saturday evening from the Sweet Grass and are buying a big lot of supplies for the winter—some 12,000 or 15,000 pounds. The best news they bring is that no action on the part of the military has been taken to put them off the reservation, and as they are there with the nominal consent of the Indians, molesting no one, it is not likely any such action will be taken; next to this is the good report from the mines. All the claims that have been worked and prospected are showing up handsomely. Fred Derwent brings in 42 ounces this time and has taken over \$3000 from his dry gulch claim, hauling the dirt over half a mile to water. Bender & White, Hagen brothers and others are also doing well. Supernaut and partners have been prospecting their claims all season and are now in condition to work to advantage in the spring, when water will be plenty. They have completed a ditch and will build a reservoir this winter, and are willing to wait until spring for the returns. By hauling the dirt to water they have taken out a "grub stake," and have not tried to do more. The whole season has been devoted to prospecting their ground, and they now know they have a good thing. The pay ground in the Sweet Grass so far discovered is limited, but of the fact that it will yield the miner ample returns there is no question. It has been demonstrated by faithful work. It is only the lazy ne'er-do-wells, who expect to find pay dirt on the surface, that have gone off and branded the camp a bill.

BOULDER DISTRICT.—*Helena Independent*, Oct. 29: The Amazon mine, owned by the Amazon Mining Company, has a shaft 250 feet in depth. The lead is crosscut at a depth of 100 feet, showing a fine body of lead ore. At a depth of 175 feet is another cross-cut, showing up three feet of concentrating ore, assaying forty ounces, in silver and twenty per cent lead. They have lately resumed sinklog on the main shaft. This company is equipped with steam hoisting works. They also possess the most complete milling, concentrating and smelting works in Montana, located one mile and a half from the mine. The concentrator is at present running on ore from the Ella mine, owned by John W. Buskett, of the Wickes company. This is one of the best looking mines in Jefferson county for the amount of work done. It is developed by a shaft 110 feet deep. They are at present stoping and working two shafts. The vein shows up three feet of ore, which they have had from the start, running about thirty ounces in silver and twenty per cent lead. The Amazon concentrator started up last Tuesday, and has proved an entire success. The works have a capacity of 25 tons per day and have all they can do. The works will prove of great benefit to the district, enabling miners to have their low grade ores put in shape for shipment. The Mona mine, owned by W. C. Jones, is located about one mile and a half from the Amazon works. It is developed by a shaft eighty-five feet in depth, showing up four feet of fine concentrating ore. He is at present running a stope; taking out about two tons of ore to the mao. North of the Mona is the Spencer mine, owned by Mr. Spencer. It is developed by a shaft fifty-five feet in depth. The lead shows up sixteen inches of pure galena ore, running ninety ounces in silver and seventy per cent in lead. Work on the Mollie McGregor has been resumed. They are crosscutting the lead at a depth of 200 feet. This company has a fine concentrator with a capacity of sixty tons per day. The mine was bonded a year ago to the Mollie McGregor company for \$60,000. The bond will expire the 6th of January. A. G. Clark, of Helena, is one of the principal movers in the enterprise.

NEW MEXICO.

CONCENTRATOR.—*Santa Fe Leader*, Oct. 28: The concentrator at the Cash Entry, Cerrillos, is being repaired by the placing of a new pulverizer, the old one being broken two weeks ago. The owners of the mine feel confident that the works will prove a success. The mills will start running next Monday.

SABINAL DISTRICT.—*Deming Headlight*, Oct. 23: Exceedingly rich specimens of ore from the Sabinal district continue to be brought into town by prospectors, and miners are continually going down that way in order to see what there is down there. They all

seem contented to stay, for we have seen none of them return except for supplies, and they are in a hurry to get back. There is something rich down there.

NEW MILL.—*Lake Valley Press*, Oct. 28: Dirt has commenced to fly preparatory to excavating for the new mill. If this process should prove a success it will be a boon to New Mexico, the value of which can hardly be realized. Indeed, all eyes are turned on Lake Valley, and should lixiviation prove a success Sierra county will flourish like a green bay tree. To Dr. Endlich will be due much credit for his perception and foresight.

GENERAL NOTES.—*Mining World*, Oct. 28: White Oaks expects a new 25-stamp mill soon. Stream tin has been discovered in Socorro county. Another big strike of free-milling ore is reported at Gold Hill. A shipment of ore from the Grey Eagle mine, Gold Hill, was made last week. The Billing smelter at Socorro is using eighteen carloads of Utah ore per week. The Glass stamp mill at White Oaks has shut down until a new boiler arrives. A new find of silver ore has been made in the Pinos Altos. It is said to run very high. Considerable ore has been passing through Organ for the railroad, from the Silver Gem mine, during the last few days. John Ross, of Organ, will concentrate forty or fifty tons of low grade ore for shipment. He will commence work next week. The Kansas City Mica Co. are shipping crude mica from their works at the junction of the Vallecito and Petaca rivers. They have ten men at work. The Water Canyon concentrator is to have its capacity materially augmented. The concentrator now being sacked for shipment vary in value from \$138 to \$300. The people of Good Hope mining camp, where J. D. Long has spent \$12,000 in improvements, are jubilant over the prospects of the mill starting up on the first of November. The Santa Teresa, Induvigan and other claims in the Socorro district, owned by Hon. F. A. Manzanares and Don Abeytia Montoya, are showing up increased volume of ore under recent developments. The Kelly mine continues to yield sufficient ore daily to run the 180-ton Billing smelter of Socorro; and at the same time Superintendent Huber continues to explore the depths below the lower workings. The main shaft in the Silver Glance, Socorro district, has attained a depth of 235 feet, and work proceeds steadily. At that depth a vein of argentiferous galena in crystallized quartz has been encountered. The Billing smelter is working to perfection, and its best advertisement now possessed by New Mexico, it having run continuously over two years without ceasing for one day, a standing and promising success. The Lone Hand, Gold Hill, made a shipment about six weeks ago, which, after all charges had been deducted, netted \$403 per ton. A considerable quantity of horn silver being in the lot is what caused the figures to run so high. Mr. Townes, of the El Paso sampling works, is in Kansas City, supposed to be making arrangements for the erection of a large smelter in El Paso. It has been demonstrated that 100 tons of good ore per day can be secured for a smelter at that point.

OREGON.

NOTES. *Jacksonville Times*, Oct. 30: Ingram & Baker are getting ready for an extensive run in their Willow Springs diggings. The Sterling Co.'s reservoir is nearing completion and will be utilized early next winter. Carter Bros. of Pleasant creek have found good prospects on the home place and are getting ready for the winter's run. Dr. Colvig and others of Rock Point precinct are engaged in prospecting and think they have found some excellent ore. G. E. Dyer, the Portland mining expert, is visiting several ledges in this vicinity, with several of which he seems to be favorably impressed. Wimer & Sons and Desselles & Connell of Waldo precinct, Josephine county, are about ready for extended operations, which will soon be commenced. The miners having been disappointed for the past three seasons, anticipate better luck this time. It is to be hoped that they will have all the water they wish. Ex-Governor Chadwick inspected his ledge in the Fort Lane district while in the valley this week, and is well pleased with it. He intends to have it thoroughly prospected before long. Moody & Bell undoubtedly have one of the best ledges thus far discovered in this section. They already have quite a quantity of ore on the dump, with several hundred tons more in sight. Work continues on the Yank ledge at Galice creek. It will be thoroughly prospected, and a gentleman who claims to know says that there is no doubt but what it will prove a paying mine. Work is still progressing on Swinden's ledge near Rock Point and better prospects than ever are in sight. We were shown some of the ore, in which considerable gold can be seen with the naked eye. The mining interests of Evans and Pleasant creeks are coming to the front again. Several promising ledges and placers are being thoroughly prospected. S. Beers, Jas. Evans, John Blalock, John Robinson and others are among those prospecting new ledges. G. B. Dyer, representing L. D. Brown and others of Portland, is now in Jacksonville for the purpose of getting our citizens interested in a quartz mill that his company propose putting here in case some inducements are given.

UTAH.

REVIEW.—*Salt Lake Tribune*, Oct. 30: The week has been one of lovely weather and the movement of the metals has been brisk. From all directions come reports of good strikes, and there is more interest taken in mining enterprises, in the way of local capital backing them than has been usual in this city. The shipments out from this city for the week ending Saturday, Oct. 24th, inclusive, were 1,650,000 lbs. The receipts in this city for the week ending Oct. 28th, inclusive, \$138,057.72 in bullion and \$36,102.30 in ore, a total of \$174,160.02. The week previous the receipts were \$110,110.54, of which \$85,154.54 was bullion and \$24,956 was ore. The Ontario sent in during the week bullion to the value of \$75,654.88, making its total output for the year to date \$1,353,327.21. For the present month a double dividend is declared by the Ontario Co., making one dollar per share, or \$150,000. Every month there has been a dividend of fifty cents per share, making \$75,000. The total dividends, therefore to the end of October, have been for this year \$325,000, or \$5.50 per share. There is nothing new from Horn Silver except the tapping of a large body of water, whether a reservoir or spring is unknown. The Stormont sent up two bars of silver on the 25th,

Hints for Lubricating.

[Written for the Press.]

An oil, designed to be a lubricant, should reduce to a minimum the loss of force occasioned by the friction of the surfaces lubricated. A lubricating oil should be smooth, sweet and neutral. A neutral oil is one that is free from harmful acids. Perfectly neutral oils, fit for lubricating, are unobtainable. The United States Government admits of 3 per cent of free acid. But a merchantable lubricating oil should be sweet and almost odorless. Beware of an oil or compound that has a bad breath, or that emits a perfume. If animal oil, any pronounced smell betrays rancidity; if petroleum oil, a strong smell suggests overheating—that the oil is burned. Perfumes, whether exhaled by oils or human beings are suspicious.

Any oil which contains acid in quantity will attack and corrode all metal with which it comes in contact. Perhaps you have noticed discoloration on the slides of the engine—dark spots on the steam-chest, that are with difficulty removed by the use of sand-paper or even metal. They are indicative of incipient corrosion. Look out for animal acid in your oil.

An easy way to find it is the following: Take a mixture of two parts clear water, (distilled if possible) with one part carbonate of soda. Fill a bottle two-fifths full of the liquid, and add as much more of the oil to be examined. Shake the mixture and let it stand awhile. There should be little precipitate. The bottle should exhibit mainly greasy globules. If, however, there is a coagulated lump, a sort of soap, in the bottom of the bottle, the oil contains too much acid.

There is another way: Put in fine small strips of copper in the oil. If, after a few days rust appears upon them and the oil takes on a green color, you may be certain of the presence of fatty acid. The denser and more extensive the rust, the greater the quality of acid.

CHARLES J. WOODBURY,
123 California St., S. F.

Mining Share Market.

There is no special change to note in the Comstock mining situation, and therefore little in the mining share market. Prospecting is still going on and assessments continue to be levied to pay for it.

In speaking of the mining on the Comstock the *Enterprise* says: It should be understood that deep developments in these mines are necessarily slow, and that all progress in any direction is costly as well. One of the chief obstacles to be encountered and guarded against is hot water. It is true that the famous hydraulic pump at the Combination shaft is now completed and in perfect working order, capable of handling any amount of water that may be accidentally tapped or met with at any point in the deep explorations, but it should be understood and appreciated that it is not ordinary cold or warm water, but scalding water, the boiling, hot and almost suffocating steam from which fills the lower drifts and very seriously impedes work, if it is not properly cared for. It will therefore be readily perceived that it is not a judicious proposition to rush a drift or crosscut recklessly forward into a point or locality where this hot water is known to exist in quantity, but whenever tapped it has to be given a chance to gradually drain out, and is run out to the pump shaft through drain boxes carefully covered up in the floor of the drift, and made to carry away its own steam. Moreover, it is good policy to handle scalding water carefully, even with the bare hands, and to manage and direct its course judiciously, even if it takes a little longer than the handling of cold or warm water.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco.

TULARE VALLEY AND GIANT FOREST R. R. Co., Oct. 29th.—The road is to be built from the most convenient point on the Southern Pacific Railroad in Tulare county to a point in the foothills of the Sierra Nevada mountains, near township—south range 29 east, and townships 15 and 16 south, range 30 east, Mount Diablo meridian. Directors, R. Butterfield, Charles F. Keller, L. A. Rockwell, Henry Miller, James B. Johnson, W. C. Owen, R. A. Gilbreath, E. G. Anderson, James J. Martin, B. G. Haskell and Martin Schneider. Capital stock is \$500,000.

ANGLO-NEVADA INSURANCE Co., Oct. 30.—Capital stock, \$2,000,000, in 20,000 shares. Directors: John W. Mackay, James L. Flood, George L. Brander, W. Greer Harrison, Louis Sloss, James B. King, Edward E. Eyre, John Rosenfield, W. F. Whittier, Jacob Greenbaum and Edwin L. Griffith.

Bullion Shipments.

North Star (for October) \$15,000; Pittsburg, Oct. 31, \$2,500; Germania, 27, \$4827; Alice, 27, \$18,584; Hanauer, 27, \$2400; Germania, 28, \$4532; Hanauer, 28, \$2800; Crescent, 28, \$4200; Vienna, 28, \$3620; Ontario, 28, \$35,249; Germania, 29, \$4598; Hanauer, 29, \$4600; Queen of the Hills, 29, \$2800; Crescent, 29, \$3750; Bannock, 29, \$5419; Antelope, 29, \$1341; Silver Chief, \$1310; Vienna, 30, \$1804; Southern Utah, 30, \$1650; Stormont, 30, \$3840; Queen of the Hills, 30, \$1200; Crescent, 30, \$800; Hanauer, 31, \$2400; Germania, 31, \$4446; Hanauer, Nov. 1, \$4500; Queen of the Hills, 1, \$2400.

Following were the ore and bullion shipments from Salt Lake city during the week ending Oct. 31st: Twenty-six cars of bullion, 636,641 pounds; 41 cars of ore, 1,220,370 pounds.

MULLER'S optometer the only reliable instrument of the kind in use. 135 Montgomery St. x

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

J. J. BARTELL—Amador and Calaveras Co's.
F. H. HORN—Nevada (State).
G. W. INGLE—Arizona.
F. L. RICHARDS—San Bernardino Co.
R. G. HUSTON—Idaho and Montana.
Geo. McDOWELL—Tulare and Fresno Co's.
HOON ELLS—Nevada Co.
W. D. PIER, Sutter and Butte Co's.
R. E. LLOYD, Stanislaus and Merced Co's.
J. WINKLER, Alameda Co.
T. BATES, Shasta and Tehama Co's.
M. L. DENNIS, Plumas and Sierra Co's.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DREW & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING OCTOBER 27, 1885.

329,252.—ANIMAL EXTERMINATOR—A. Anderson, San Jose, Cal.

Woodbury Oils.

Pure, Perfect, Uniform!

The WOODBURY OILS are in use on the Central and Southern Pacific Railways, and on nearly every railroad and steamship line on the coast.

We are not agents for other manufacturers, but have our own works, and adapt here all our oils to the requirements of home machinery and our climate. We can show recommendations and records of tests, showing a saving to our customers of 60 per cent on their lubrication last year. Address

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

Manufactured only by

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Cokes having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Cokes, which is for sale in quantities to suit purchasers.

MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS,
embracing machinery of LATEST DESIGN and
MOST IMPROVED construction. We offer our cus-
tomers the BEST RESULTS OF 35 YEARS' EX-
PERIENCE in this SPECIAL LINE of work, and
are PREPARED to furnish from SAN FRAN-
CISCO or CHICAGO, the MOST APPROVED
character of MINING AND REDUCTION MA-
CHINERY, adapted to all grades of ores and SU-
PERIOR to that of any other make, at the LOWEST
POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DE-
LIVER in COMPLETE RUNNING ORDER,
in any locality, MILLS, CONCENTRATION
WORKS, WATER JACKET SMELTING
FURNACES, HOISTING WORKS, PUMP-
ING MACHINERY, ETC., ETC., of any DE-
SIRE CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD
ores of NEW and ORIGINAL DESIGNS, covered
by LETTERS PATENT. No other Furnace CAN
COMPARE with these for DURABILITY, and in
CAPACITY for uninterrupted work. MORE
THAN 150 of them are now RUNNING in various
parts of THIS COUNTRY, as well as many in
FOREIGN COUNTRIES, giving results NEVER
BEFORE ATTAINED as regards CONTINUOUS
running, ECONOMY of fuel, AMOUNT and QUAL-
ITY of BULLION produced. These CLAIMS have
been PROVEN BY RESULTS in ANY NUM-
BER of INSTANCES, and the GREAT SUPER-
IORITY of this SYSTEM of smelting ores DE-
MONSTRATED BEYOND QUESTION. COM-
PLETE PLANTS furnished to order of any CA-
PACITY, with ALL IMPROVEMENTS that ex-
perience has DEMONSTRATED as VALUABLE
in this class of work.

Beyond question the cheapest and
most effective machine of the kind
now in use adapted to all grades and
classes of ores.

This machine has been THOROUGHLY TESTED
for the past TWO YEARS, under a GREAT VA-
RIETY of CONDITIONS, giving most EXTRA-
ORDINARY results FAR IN ADVANCE of
anything EVER BEFORE REALIZED. A re-
cent COMPETITIVE TEST at the Carlisle Mine in
Mexico, showed an ADVANTAGE OF OVER 30
PER CENT in favor of THE DUNCAN. The
amount SAVED OVER THE TRUE being suffi-
cient to PAY THE ENTIRE COST of the ma-
chines EVERY MONTH OF THE YEAR. One
of its MOST VALUABLE features is as an AMAL-
GAMATOR. It saves all THE AMALGAM GOLD
and SILVER that ESCAPES the BATTERIES,
PANS or SETTLERS, making the machine worth
MORE than ITS COST for THIS PURPOSE
ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist
and affording means for the continuous operation of a
Pump or Blower, without interfering with a hoisting ap-
paratus. It is made entirely of iron, no piece weighs
over 300 pounds. At the ordinary speed of a horse, a
1,000-pound bucket of ore may be raised 120 feet per
minute. The hoisting-drum is under the complete con-
trol of the man of the shaft, and is capable of carrying
500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS,
(\$575 00), F. O. B.**

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED.

**PRICE, FIVE HUNDRED AND FIFTY DOLLARS
(\$550.00), F. O. B.**

THE "TRIUMPH" TRIUMPHANT!

**THE
"TRIUMPH" ORE CONCENTRATOR.**

In a competitive trial recently had between two of the "Triumph" Ore Concentrators and the same number of "Frue" Vanning Machines, at the mill of the celebrated gold producing Original Empire Mill and Mining Company, in Grass Valley, Nevada County, Cal., the "Triumphs" produced thirteen and fifteen one-hundredths (13.15) per cent more concentrations than did the "Frue" Vanners, during a run of twenty-four consecutive days, or a net gold coin result of \$199.15, or \$8.30 per day, in favor of the two "Triumph" Concentrators.

These returns do not include the value of the amalgam saved by the "Triumphs" during the test, which will add to the net gain. The form of construction of the feed bowl is such that considerable amalgam is necessarily saved, which is lost on the "Frue" Vanners. This trial was conducted under the personal supervision of the Manager and Superintendent of that Company, in a strictly fair and impartial manner, and with the sole view of determining, in the interest of that Company, the merits and demerits of the respective machines by a thoroughly practical test. A relation of the course of procedure, a concise analysis of assays, and a tabulated statement of the net bullion results, with accurate deductions therefrom, will soon be published in Circular form.

The superiority of the present construction of the "Triumph" over the form originally introduced, together with the demonstrated results of the above, and other trials had with the "Frue" Vanners, induce us to and we hereby accept the Challenge of \$1,000, flouted by the Agents of the "Frue Vanning Machine Company," and hold ourselves in readiness to enter into a second competitive trial for that sum, at such place and upon such terms and conditions as may hereafter be mutually arranged.

We guarantee purchasers against all costs, expenses or charges incurred by reason of any infringements of any existing patents.

Concrete Construction.

Concrete may be described briefly as pieces and particles of rock or like material aggregated together with lime or cement. The origin of its manufacture is unknown. The massive ruins in Italy testify to its durability, and of its extensive employment by the Romans. Since the introduction of Portland cement, the use of concrete has greatly extended. In England, where the first cement was manufactured, Drake states that thousands of concrete buildings have been erected of late years. The great desirability of concrete as a building material is well recognized and rapid strides are being made in its application. Rapid as has been the increase of concrete building during the past few years, the progress would have been still greater had it not been hindered by the general lack of knowledge on the subject, the great cost of molding or shaping the material, and the want of adequate appliances for mixing the concrete.

There are many localities where sand rock or gravel can be obtained at a nominal cost, in which concrete could be profitably introduced by any metallurgical man. And in these same districts are men plodding along in the grooves of better-known trades, who by turning their attention to concrete construction could establish themselves in a good business. Of course it would be necessary to purchase a license from the inventor of the more improved systems of concrete building, in which case buildings can be put up with unskilled laborers, provided the men are intelligently directed.

On this page we give an illustration of a building in process of erection on the system invented by Ernest L. Ransome of this city. Mr. Ransome has received patents covering building construction, concrete mixer and a concrete apparatus for molding walls, houses and other buildings.

The engraving gives an isometrical view of a building in course of erection with part of the scaffolding removed. Ransome apparatus for molding the walls consists of slotted standards, which being placed in pairs, one on either side of the site of the wall and bolted together, hold in place the mold boards, between which the concrete is placed. These standards are arranged to slide upwards upon the outer face of the mold boards as the wall progresses, and are made to conform to any breaks or projections that may be required in the building.

The molding boards may be of any size. If they are permanently required for the apparatus, they should be surfaced and squared, and about 1½ inches thick, 6 to 12 inches wide, and as long as could be conveniently obtained or handled. If on the other hand, by reason of the location or other causes, they are only

needed temporarily for this purpose, then their dimensions should be determined by their future use. For instance, if they are subsequently needed for flooring, then flooring could be used; if fencing is wanted, then use fence boards; if planks are required, then let planks be taken. In using them for the mold the boards or planks are but little damaged, the bolt holes required in some of them are not large and could easily be filled up.

Ordinary bolts may be used for connecting the standards together, but those having winged nuts will be found more convenient. The washers should be of good size.

In building retaining walls, posts are inserted in the face of the bank and sunk below the foundation of the wall at intervals of from five to ten feet, and the slotted standards are attached to these by means of lag screws.

For a plain building, say 100 feet long by 50 feet wide and 50 feet high, the cost of the apparatus, irrespective of height, would not exceed \$150 and the expense of working it would not be more than a cent per cubic foot of concrete. After building a wall the apparatus is good for 10 or 20 more. By this system the first cost is small and the expense of working slight. There is no difficulty in keeping the wall plumb,

Not Wasted.

The statement is often made that millions of dollars have been wasted and lost in useless work on unproductive mines on this coast. It is not lost in the sense that money is lost in a shipwreck or a fire. It simply changes hands. Men with means go into a mining speculation and employ men who work by the day to do the work on the claim. They buy machinery, provisions, tools, and sink shafts, run tunnels, and do general mining work, which they pay for. The money goes into the hands of the people who make the machinery, tools, etc., and those who do the mining work. And the work in going on gives employment directly and indirectly to many persons, according to the magnitude of the interests involved. So, now, if a mining venture proves a financial failure to those who have invested, the region where the mine is situated gets the benefit of the money spent.

Even unlucky mine ventures add to the general wealth. There are few which do not produce some results in gold or silver, even if the amount is not sufficient to pay profits, and every cent taken out adds so much to the world's wealth. If people spend \$100,000, and only get out \$50,000, there is \$50,000 more in circulation than before that amount was taken out, and the \$100,000 is yet in existence, but in other than the original hands.

This argument may seem specious and would not be satisfactory to the men who have put in the money and lost it; but they have simply lost it. It is gone from them and is in some one else's hands. It is not lost from the world's circulation.

But we often hear of heavy losses in mining, which are merely losses in stocks. Men pay \$10 a share for stock and it goes down to \$1 a share. The appreciation or shrinkage of

stock makes and loses many fortunes. But it is not of this form of "mining" we are speaking. It is in legitimate mining work where money is paid men to develop property, in hope that returns may be made on the investment from the product of the mine itself. Of course a great deal of money is expended on unproductive properties. Yet, on the whole, there is no doubt that taking the mines of the country at large, very heavy profits have been made on the investments.

RELOCATION.—If the locator admit another to the possession with him, this will amount to an abandonment *pro tanto*, and a re-taking by the party admitted, upon which they will become interested in the claim, jointly or otherwise, according to the terms of their agreement. In these particulars the rule is the same when applied to the relocation of an abandoned claim.

ISOMETRIC VIEW OF CONCRETE BUILDING IN COURSE OF CONSTRUCTION

The *modus operandi* is as follows: The foundations being prepared and the standards and lower molding boards all in position, concrete is put into the mold continuously, layer after layer. Molding boards are added from time to time, as needed, until the concrete is brought to about the top of the standards. The bolts are then slackened, a set at a time, and the standards pushed up a few inches, or a foot or two, dependent upon the character of the work.

As soon as the lower bolts are in the way of the upward movement of the standards they are withdrawn and replaced at the top of the slot. The moulding boards, liberated by these movements, are reused above those already placed as often as needed.

This action is repeated as often as may be necessary to obtain the height desired. It forms a continuous operation and offers no interruption to the filling in of the concrete.

and there is no trouble in molding projections if desired.

The large warehouses recently built for the Arctic Oil Works, on the Potrero, were constructed in this manner by the patentee of the system. The fire-proof roofs of these warehouses were also built by him. Mr. Ransome has been of late building many concrete floors for foundations for machinery, etc., the largest floor being that of the Starr & Co. Mills, at Wheatport, Contra Costa Co., where they have 50,000 square feet of surface. The extreme foundations of this mill were also built of concrete. In the piers, arches and floor platforms there are 140,000 square feet of concrete.

Mr. Ransome, whose office is at 402 Montgomery street, is prepared to sell licenses and territorial rights for his various inventions in connection with concrete construction, and give suitable instruction so that people can build for themselves.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

The Cœur D'Alene Mines.

[Written by our Special Correspondent R. G. HUSTON.]

(Continued from last week.)

The quartz interests of the camp now seem to be very promising, and if they continue to develop in future as satisfactorily as they have thus far, it will not be long before the outside world will find out where the Cœur D'Alene mines are. In the short space of two seasons there have been nearly 2000 locations made, and, of course, many more will be made. Many will certainly be worthless, but undoubtedly there are some good ones now known of. The ores are galena, chloride, carbonate, grey copper, native and antimonial silver and free milling gold ores. Several properties have been disposed of to parties who evidently mean business, and by the opening of another season there will surely be several mills erected on the different properties as they have already contracted for them. Of course, for the most part, the quartz to this date is purely speculative, with one exception—the Golden Chest—but there is no doubt in my mind but there are some fine properties here. I will note

A Few of the Districts

And the locations and development. For the main I am indebted to Mr. H. G. Longer, assayer in Murray, and Phil. A. Marksar. Canyon Creek district is some 25 miles southeast from Murray. The first, and really the best developed, lead in the country is called the Tiger mine, having a tunnel in 350 feet. They have a true fissure vein five feet wide, and have from 2500 to 3000 tons of ore on the dump which assays, as you take it from the pile, from 40 ounces to 200 ounces silver to the ton. This property has just been sold to Messrs. Glidden and Burke, of Montana, for \$40,000, and is considered a very cheap bargain to the gentlemen investing. Many think that they will get their money out of the ore on the dump alone. They are gentlemen of ample means, and will, no doubt, develop it as rapidly as possible.

The Diamond Hilt is in the same district and carries some chlorides and native silver, and from choice rock assays have been obtained that ran as high as 3000 ozs. silver to the ton. It is a fine prospect but not developed enough to be a satisfactory showing for mine buyers.

Orinogo, owned by Colonel Wallace, is a galena ledge and is claimed to assay very high; is also very wide but comparatively undeveloped.

The Poorman is an extension of the Tiger lode but is not so well developed, but contracts have been let for tunnels to be run in it this winter. There seems to be no reasonable doubt but that it will, on development, show up well.

The Nigger Prairie district is some six miles south of the Tiger mines on the old Mullan road, and shows large deposits of galena and chlorides, and there is some talk of a smelter being erected at Placer Center, the trading point of this district.

Yreka district is close by the latter and the ores are similar, the peculiarity of these locations being that they are in such immense bodies, mostly a low grade silver ore and carrying about 50 per cent lead. The location is very late and consequently there has been but little done to develop it as yet.

Beaver Creek District.

Sunset lead is a well-defined vein; croppings the full length from five to twenty feet wide; solid galena and assays run from 30 ounces to 70 ounces of silver per ton, with 70 per cent lead. This may, on further development, make a very fine showing.

Silver Tip is an extension of the Sunset, and the character of the ore is similar.

The Tough Nut has a tunnel in 75 feet which shows nine feet of galena ore mixed with quartz and is also thought to be valuable. There are many others in this district, but nothing has been done only to make the location, and these are not worth mentioning. The woods are full of prospective millionaires, and I hope they will all realize their fullest hopes.

The Buckeye Boy lode, located on Dream Gulch, was owned by Frank Reed, who has just sold a one-half interest in the location for \$40,000 to Murray Keller, who also contracts to erect a mill immediately. He is from Louisville, Ky., and from all that can be seen, should certainly congratulate himself on the possession of as fine a piece of free-milling gold ore property as there is in any country. Specimens I have seen are literally spangled with gold. I think Mr. Reed has at least \$10,000 worth of fine specimens which he has picked out whilst developing his lead.

The Skookum lode is located on the Main creek near Osborne; is also free milling gold ore and is a well-defined ledge. It has also been disposed of to Louisville parties for \$12,500, and they have contracted for a mill. To all appearances next season will be the opening day for the quartz mines in the different districts in and around the Cœur d'Alene.

Summit District.

The Golden Chest mine is on Reeder gulch, and is a free-milling gold lode. It has the only

mill that is in the camp, and at the present time is working only five stamps, although it is a ten-stamp mill. The reason for only working five stamps is want of water, but the large ditch being brought around to these hill placer diggings will soon be down that far, and then they can get plenty of water. The results are thus far very satisfactory. The Golden Chest Mine and Milling Company is composed of Louisville, Ky., parties. The Kentuckians seem to have the nerve to put their money in, and they are satisfied thus far with returns.

The Mother lode is located on the main creek opposite the mouth of Reeder gulch, and some think is an extension of the Golden Chest mine. As much of it as has been uncovered is virtually sheeted with gold, but the owners have only made a small showing, running a tunnel in on one side of the ledge for about 40 feet, and have not touched the ledge proper. Whether it is because it looks pretty and they are afraid they will spoil the looks of it, or that they fear their wealth will vanish into thin air on development, is a conundrum I was unable to solve to my satisfaction. I can only say that I never saw any free-gold rock its equal in richness. There are six men interested in this mine—enough muscle to develop it without the aid of capital. It was one of the first locations of quartz in the camp, and yet it is only a prospect. Other mines have been located and developed, so that parties could satisfy themselves that they were bonafide mines and have been sold, but the Mother lode still lies dormant, and it looks as if the only thing the owners knew how to do was to hold their breath and ask a fabulous sum for their mine.

The Cœur D'Alene Bedrock Flume Pool.

The main creek is the base of operations of the most gigantic placer mining scheme I have ever seen. A company have organized with \$5,000,000 capital to push this enterprise to a completion as rapidly as ample capital will admit of. The proposed length of this flume is nine miles; it is to be in three compartments, two of five feet each and one of four feet for a clear-water channel. It is to be rifled with railroad iron. At the time I was down at the works there were about 400 men at work, and they were hiring every man who came along and wanted work. One gang was chopping down the trees on the right of way; another gang followed those and cut these trees up into lengths that could be handled. After them came the log-rolling gang and grubbers, and then came a gang loading these stumps with giant powder and blowing them into atoms, and then came a regular army of graders, and they were strung along for a mile—two men to each 25 feet of the ditch, throwing it out some 20 feet wide and to a regular grade of about one and three-fourths or two inches to the rod. The place looked like a hive of bees, and is certainly very ably operated. The general foreman on the works is Mr. Patrick Flynn, and he is evidently an old hand with a crew of men, as he has them so well arranged that he can see at a glance as he passes along that each man is doing his duty. The men, as a rule, are first-class men, and do their work with a will.

Mr. John Ryan is the contractor. The first contract signed was for the sum of \$650,000—pretty large contract for outside camp like this. The officers of the company are as follows: C. A. Weed, Manager, New York City; A. G. Sanford, Secretary, New York City; Thomas J. Burke, Manager, Denver, Colorado; R. L. Hopkins, Manager, Murray, Idaho; W. B. Hepburn, Counsel, Murray, Idaho; John Ryan, contractor, Albany, New York. They evidently mean business, as they have bonded a large quantity of ground up the gulch, and are paying their men off promptly twice a month—1st and 15th. That gives it an air of solidity that they could acquire in no other way. The proposition was so extensive that the most of the people were inclined to look upon it at the start with suspicion, but at the present they have settled down to facts, and are happy to know that bedrock is likely to be reached in the main creek.

The agricultural interests I found almost monopolized by an old mining friend of the early placer mining days of Montana. Mr. W. G. Stagner and his worthy lady are located on a ranch a short distance below Eagle City. I spent a very pleasant evening with them, and next day Mr. Stagner went with me, and together we secured a number of staunch subscribers to the MINING AND SCIENTIFIC PRESS. May their crops never be less in quantity and price than this year, is the worst wish I have for them, as potatoes are worth three cents per lb., and cabbages six cents per lb.; hay and grain are about three and a half to four cents per lb. So it is just now a paradise for a rancher.

Eagle City, at the time I was there, was looking up a little and they had some hopes that this movement by the Flume Company would permanently help Eagle, but the only question I see about it is whether they will strike bedrock near Eagle or not. I am afraid that is an impossibility when the amount of fall the gulch has is considered.

Murray has some 1200 or 1400 inhabitants, and is well supplied with the usual business houses. The Palace hotel is owned by Caldwell & McCorkindale; restaurants are run by Messrs. Bennington and Beusendefery; saloons, by Messrs. Garrison, Wolf, Goetz & Hanley; merchandise by R. McKenzie, G. N. Culver, J. R. Marks & Co.; drugs, by Messrs. Bass & Ingalls, and the financial interests are ably taken care of by the Bank of Murray, C. L. Dahler President, Chas. Hussey Secretary, Warren Hussey Cashier.

The news interest is ably represented by an old San Franciscan, Adam Aulbach, who edits the Cœur d'Alene Sun, with whom I spent a pleasant hour, and he also gave me all the points that an old resident would naturally be able to give a transient new-comer. I was surprised when I was told that the elevation of Murray was less than 3000 feet, as I imagined from the amount of climbing I did getting in there that it was not less than 5000. Appearances are many times deceitful, particularly when climbing mountains.

The Thompson Falls have great hopes of their becoming a quartz camp of no mean proportions, and there is a strong probability of their realizing their hopes. The Silver King mine is ten miles northeast from Thompson, and some four miles from the railroad. From developments and assays obtained it will surely be heard of in the mining world. They will soon have a tunnel in 100 feet, and from a beginning the size of a person's hand the ledge has enlarged to two feet of solid ore. The assays are surprisingly rich, running from 150 ounces silver as the lowest, to 4712 ounces silver as the highest, and from \$20 to \$22 gold, and 40 per cent copper. Samples of the rock which I have seen were simply all mineral. They have nearly 100 tons of ore on the dump. The lucky owner of this property is Mr. W. H. Anderson, of Portland. Mr. Anderson was formerly a conductor of the N. P. R. R., but thinks he is now well enough fixed to quit railroading, and there seems to be no reasonable doubt of his realizing on his mine, as there are a number of parties looking after it. There are many other locations in or near this point, but this is the principal one, and the only one that had made any developments worthy of note.

Cobalt and Nickel Mines.

EDITORS PRESS:—A great deal has been said of late in the papers concerning the nickel and cobalt mines in Churchill county, Nevada, and considerable of it is entirely false. In the fall of 1881, I went into the east range of mountains in Churchill county, to expressly prospect for nickel and cobalt, and on the 29th of November, 1881, I located the following claims: British Queen, the Monarch, the London, Emperor, President and Empire. The London fell into the hands of Wm. Bell and A. J. Mason; in what way it is not necessary to mention. The Emperor is the richest mine by far among the lot; is very large and well prospects down to water level; is 38 feet between walls, and there has been about 140 tons of as rich cobalt and nickel ore shipped to Liverpool as ever went from any country. I have about 2000 tons of second class ore now on the dumps, and am still taking out ore for shipping.

GEORGE LOVELOCK.

PROSPECTING.—Glorious weather for going into the mountains, holling the hard-hearted bean and hunting up deposits of gold, silver, copper and lead. The days are warm and the nights just cool enough to keep one's nose in fine snoring condition. There is here a large territory to prospect. Most of it has been scanned, but that is all. "Float" will have to be found and some digging done in order to find "blind" ledges, which are generally the richest. Prospecting in fine weather such as we usually have in Arizona is glorious employment. You take a donkey, load him down with provisions, tools, bedding and a little stimulant, put your gun across your shoulder and go into the deep woods; make camp, cook your meal, take a smoke and a stroll for indications that will lead to quartz, ore or game. You need have no fear of Indians, for there are none outside of Tombstone. If you see a mouse, don't shoot; but if you see a squirrel, jack or cotton-tail rabbit, deer or bear, let him have it. The water you will find will be good and pure; the scenery will make you feel that, although you are a man and master of almost everything around you, "creation is much greater than you are, and the Creator, who made great trees to protect you in life and furnish your coffin when death takes you, is grander, greater, more merciful, than imagination can picture." We like prospecting, but fate has divorced us from it and detailed us to scratch down stuff for "wise" men to pick to pieces.—Prescott Courier.

WASHINGTON TERRITORY COAL.—The output of coal from Washington Territory mines during the year ended June 30, 1885, was 380,250 tons, from the following mines: Newcastle, 149,048; Renton, 30,397; Cedar River, 14,573; Black Diamond, 10,562; Carbon Hill, 135,926; South Prairie, 34,313; Tacoma, 5431. The Newcastle, Renton, Cedar River and Black Diamond mines are in King county; the Carbon Hill, South Prairie and Tacoma mines, in Pierce. During the year under review the King county mines yielded 204,480 tons; the Pierce county mines, 175,770. The Cedar River and Black Diamond are new mines, the others old ones. During the current year the new Franklin mine will go to still further swell the production of King county coal. About 2,500,000 tons of coal have thus far been mined in Washington Territory, 1,700,000 of which were from the mines of King county; about half of the remainder from Pierce county, and the other half from Whatcom.—Portland Oregonian.

THEY have made a new and rich strike in the Drum Lummon mine, M. T.

The Original Discovery of Gold in California.

It was in Alvarado's time, and about March, 1842, that gold was first discovered in Alta California. It is true that among the various reports of Drake's voyage, there is one which, in speaking of his landing at New Alhion, in 1578, says that "there is no part of earth to be here taken up, wherein there is not a reasonable quantity of gold or silver." But it seems probable that this statement was an interpolation. Whether so or not, it is very certain that Drake saw neither gold nor silver on the coast. There is no pretense that he did in a very minute and circumstantial narrative, entitled "World Encompassed," by his chaplain Francis Fletcher, who would hardly have omitted a matter of so much importance, if known; nor is there any reference to gold or silver in any of the narratives of the sailors appended to and published with the "World Encompassed." For these reasons, and on account, also, of the very general, indefinite, and interjectional character of the statement itself, it must be rejected as a fabrication. It is further true, that there were reports that Captain Jedediah S. Smith, the first American who arrived in California overland, found gold in the Sierra Nevada mountains about the year 1826; but his discovery, if it were true, took place on the eastern side of the Sierra, and not within what is now known as California. But in 1841, Andres Castillero, the same person who afterwards discovered the New Almaden quicksilver mine in Santa Clara county, while traveling from Los Angeles to Monterey, found near the Santa Clara river a number of water-worn pebbles, which he gathered up and carried with him to Santa Barbara. He there exhibited them, said they were a peculiar species of iron pyrites, and declared that, according to Mexican miners, wherever they were found, there was a likelihood of gold being also found. A ranchero named Francisco Lopez, who was living on Piru creek, a branch of the Santa Clara river, but happened at the time to be at Santa Barbara, heard Castillero's statement and examined his specimens. Some months afterwards, having returned home, he went out on a search for strayed cattle. At noon, when he dismounted from his horse for the purpose of resting, he observed a few wild onions growing near where he lay. He pulled them up, and in doing so noticed the same kind of pebbles as those to which Castillero had called his attention. Remembering what Castillero had said about them, he took up a handful of earth, and upon carefully examining it, discovered gold.

The news of the discovery, the exact location of which was a place called San Francisco, about 35 miles northeast of Los Angeles, soon spread; and in a few weeks a great many persons were engaged in washing and winnowing the sands and earth in search of gold. The auriferous fields were found to extend from a point on the Santa Clara river, about 15 or 20 miles above its mouth, over all the country drained by its upper waters, and thence easterly to Mt. San Bernardino. On May 14, 1842, Alvarado wrote to the prefect of the district, reproving him for not having given official notice of the discovery, and directing him to gather and forward an account of all circumstances of interest relating to the gold for transmission to the supreme government. From that time to this day, there has been more or less working of these mines; but no places of very great richness have been found, and none to compare with those afterwards discovered on the tributaries of the Sacramento and San Joaquin. Taking the whole country together, however, from the Santa Clara river to Mount San Bernardino, a very considerable quantity of gold has been extracted. During the first year, though the methods of working were exceedingly rude, it is said that Lopez and a partner, named Chas. Barec, with a company of Sonorians, took out about \$8000. In November, 1842, a package of about 15 ounces of the gold was sent by Abel Stens to the United States mint at Philadelphia; and, upon assay, it was found to be worth a little over \$340.—Theodore H. Hittell, in November Overland.

A PROSPEROUS INSTITUTE.—Reports have been forwarded as follows to the trustees of the Mechanics' Institute: The librarian reported the receipts for October to be \$1886.17; rents received for the Pavilion, \$970.77. The report of the ticket committee showed that 37,000 children had been admitted free during the late fair. The amount taken in at the door was \$35,625; outside subscriptions and sales raised the amount to \$43,226. Total amount, including sales of privileges, \$48,470.40. The Treasurer reported that \$23,000 had been paid by the institute since the fair on mortgage debts. The Committee on Lectures and Classes reported in favor of holding a mechanical drawing, a Spanish and a geometry class, and that each scholar should be assessed \$5 for the season.

THE MANUFACTURERS.—At the annual election of the Manufacturers' Association, the following were elected Directors: W. T. Garratt, N. W. Spaulding, James Spiers, Irving M. Scott, William Harney, A. W. Starbird, Charles J. Woodberg, Charles Bundschu, A. S. Halliday, Charles R. Steiger and William Fanll.

MECHANICAL PROGRESS.

Bending Cast-Iron.

The quality of cast-iron in softness—yielding to tool working—and in toughness has been greatly improved within the memory of many workers who are not old men. The crisp, brittle, hard character of cast-iron has been changed to a material of a purer condition, and therefore better nature.

One of the peculiarities of modern cast-iron for machinery purposes is its flexibility, its capacity of being moved from its unaltered position and retaining its new contour. In the older time it was necessary to peen a casting in order to permanently bend it, and this peening was rarely more than skin deep. The action of peening is simply to expand the surface of the casting by the quick, sharp blows of the peen end of the machinist's hammer—this unattached part must, perforce, give to this persuasion. The consequence is that the hammered side is stretched, just as hammering will stretch lead, or silver or copper, or any malleable metal. But the objection to this peening process is that the after-working by the file or the planing tool may destroy all the work done by the peen end of the hammer.

But it is possible to permanently bend cast-iron without resort to such heroic methods as peening, and the ruders of beating to redness in a forge fire, bending while soft, and plunging into cold water; the last so risky of breaking the casting that it is seldom tried except on cheap stuff like grate-bars or similar traps. Good cast-iron can be bent and keep its bend without the slow process of peening or the risky one of bending under intense heat and chilling in cold water with the chance of breaking. And this quality is sometimes handy.

In a cotton-mill for spinning peculiar yarn, the leaders on a spooler require to have a decided curvature near their heads. For convenience in finishing and fitting, and for economy in production, castings were preferable to forgings. These castings were made flat, but after being finished they were heated over a blaze and bent under a lever. The amount of bend was more than 30°.

A casting was made recently which required two turns or bends in its length, the casting weighing something over three hundred pounds. The superintendent determined to make the casting straight, plane and finish it, and afterward bend it to shape. This was successfully accomplished. The curved pattern would have been costly, the resultant casting might have been faulty, and the band dressing and finishing of the double curved casting would have made the piece cost more than if forged. But a forged piece of wrought-iron was just what was not wanted; it was a casting, and it was made.

Where the bends were to be made were stationed alcohol lamps, the piece being suspended between proper supports. After the underside being heated to a degree that would have drawn bared steel to a straw color—as a supposable degree of heat—a pressure, by weighted lever, was introduced on the upper side of the casting. As the lamp was moved from point to point, it was surprising to see how the iron yielded to the pressure and the heat. A curve was made that could not have been finished by planing, and yet the bent casting retained its finish, only the discoloring by the lamps being necessary to be removed by emery cloth rubbing.

A crooked casting, withdrawn out of line by injudicious pattern making and lack of sensible molding in the foundry, was about to be thrown on to the scrap heap, at a loss of nearly a hundred dollars. It was straightened to usefulness simply by the careful use of two gas flames, diffused by wire netting, and by the use of weight. It is quite possible to bend or to straighten cast-iron to an appreciable extent by quite a low degree of heat, if the heat is judiciously applied; a gradual heating of the side to be elongated by the heat that can be controlled, and the simultaneous persuasion of weight, lever or crew, will do wonders on such a material as this cast-iron that is usually considered to be of too friable, untamable and brittle a nature to be much beyond stone in resistance to tension, but even stone will bend.—*Scientific American*.

TEMPERING BRASS.—A correspondent of *Mechanical Progress* having stated in an article written for that journal that "brass cannot be tempered," another correspondent replies as follows: This differs with my daily experience. Brass, not hard by mixture, but by compression, either rolling, hammering, wire-drawing, or any other process which compresses the particles of metal, can be, and is, tempered regularly, just as easy and in the same manner as you would temper an equal-sized piece of hardened steel, viz., by heat. By placing a small piece of polished steel on the brass object to be tempered, and applying the heat so as to affect equally the brass and steel, you will know by the color of the steel the temper of the brass, which by this process may be tempered in exact proportion to every shade of color of the steel.

TEMPERING FROST DRILLS.—A cotemporary says: Drills, reamers, taps, etc., are first hardened by heating in a bath of prussiate of potash and salt, in about equal proportions, melted (without water) in a cast-iron crucible, and held at just as low heat as will answer,

and will have the steel harden. The degree of heat varies considerably with different kinds of steel. The temper can best be drawn by placing the articles in a tight oven kept at the required temperature, as by this method the operation may be carried on very slowly. After drawing the temper the work has to be straightened. This can be done by heating the drills up to nearly that point of drawing the temper which makes them about as pliable as annealed steel.

A Possible Large Demand for American Iron in China.

There are strong influences at work that are quite likely to lead the Chinese Government to begin the construction of an extensive system of railways with a view to provide for military exigencies as well as for commercial ends. It is reported that the plan for such a system of railroads has been so far advanced that already the Chinese are negotiating for the means in Europe for its execution, and with such a plethora of idle money as now exists it would seem that such a government as China should have no difficulty in placing a loan to be thus employed to ends that are creative and not destructive.

In that event, a demand for a vast quantity of iron and steel will be created which, with proper management, might be turned to the material advantage of the American iron and steel industry. We certainly should be able to compete favorably with Europe in a very great deal of the material and appliances used in the building of Chinese railroads. Every exertion should be made in this country to win a liberal share of the industrial advantages to the West that are sure to be the result of an extensive construction of railroads in China.

The *Railway Register* is quite sure that most of the railway construction of the next ten years is to be in China. The rulers of that ancient nation, for a long time supposed to be in its dotage, have determined that it shall be supplied with modern transportation facilities.

Our iron men are not indifferent to the possibility of this trade. Gen. Wilson was recently sent to China as the accredited agent of an alleged syndicate for constructing Chinese railroads. Should he offer better terms than the English and German syndicates, that are known to be competing for Chinese favor, we shall obtain a new opening, not only for the investment of American capital, but also for American iron and steel rails, and American locomotives, along with employment of American engineers, and whatever other material and personnel may be requisite for providing "cheap John" with all the railway facilities he may desire—to say nothing of watered stocks, of which, no doubt he will get a plentiful supply in due time.

A MECHANICAL STRIKER.—A colored man, Minnis Haden, of Montgomery, Va., has invented a mechanical striker which is worked by foot while the smith has both his hands free to hold his iron and use the small hammer. To a listener, it is said, the blows come as naturally and as rapidly as if there were two men handling the hammers in the old-fashioned way. The machine, by an easy motion of the foot on the treadle, strikes a harder blow than any man can strike, and can be made at will to strike as light a blow as may be needed. The device can also be used in driving a drill for blasting purposes at any desired angle. The machine is said to be cheap, profitable and not heavy.

TEMPERING SPRINGS.—A correspondent of the *Blacksmith and Wheelwright* says: "My way of tempering springs for use above or below water is as follows: I first forge from good cast-steel, hammering edgewise as little as possible, and then heat evenly in a charcoal fire. I do not blow the bellows, but simply lay the spring in the fire and let it come to a cherry red. I next dip it in pure lard oil, then take it out and hold it over the fire while the oil flares all over the spring. I then lay it in the dust on the forge and let it remain there until it is cold. Then the job is done. Springs should never be filed crosswise, but should be always filed lengthwise for a finish.

TO TEMPER COLD CHISELS, TAPS, ETC.—When tempering cold chisels or any other steel articles, heat to a very dull red and rub with a piece of hard soap; then finish heating, and harden in clear, cool water. The potash of the soap prevents the oxygen of the atmosphere from uniting with the steel and forming rust or black oxide of iron. The article will need no polishing to enable the colors to be seen. This will be appreciated when tempering taps, dies or very complex forms not easy to polish. Never "upset" a cold chisel. It is sure death to the steel.

EFFECT OF CONTINUOUS HEAT ON CAST IRON. M. L. Forquignon, in the *Comptes Rendus*, states that from experiments on heating cast-iron in vacuum to a temperature of from 900 C. to 1000 C. for several days without melting, he finds that metal becomes malleable and its surface uniformly black, and dotted with black grains of amorphous graphite, the formation of carburet of iron or plumbago being a function of the temperature.

FARADAY proved the magnetic condition of all matter, and that magnetism, unlike electricity, cannot be insulated.

SCIENTIFIC PROGRESS.

The Late Flood-Rock Explosion.

Elaborate preparations were made at various points within a range of about 200 miles of New York to detect and record any tremors of the Flood Rock explosion which might reach their respective stations. Seventeen parties were thus stationed. Of this number about one-half seems to have given up watching after eight or ten minutes past the time set for the explosion arrived. The task of watching their instruments was too great for the majority of the observers, although this delay did not exceed thirteen minutes, and much valuable information was thereby lost to the world. The instruments were very delicate, and capable of exhibiting the slightest undulation which might reach the same. The observations were expected to be of much value in the study of the force, speed and extent of earthquake disturbances. It appears that the disturbances were quite extensive for one whose initial point was so near the surface. One of the most interesting reports was made by Prof. W. A. Rogers, at Harvard College, Cambridge, Mass. This report was read at the meeting of the American Society of Arts, held at Boston, Oct. 10th, and given in *Science* as follows:

Professor Rogers stated that at 11:17:30 by the chronometer a very decided commotion of the surface of the mercury was observed. About 15 seconds later the rumble of an ice-wagon was heard at a distance of 1000 or 1300 feet from the observatory. From this instant the effects of the disturbances by the wagon and of the explosion were combined, but the disturbance waves from the latter cause were so greatly magnified beyond anything he had ever before observed that he thinks there can be no reasonable doubt of their reality as the result of the explosion. A second and still more violent commotion was observed 10 or 15 seconds later, and a third even greater disturbance occurred about the same length of time following the second. At 11:18:15 A. M., the entire surface of the mercury under the objective appeared to sway back and forth over a space certainly as great as one five-hundredth of an inch. This action continued eight or ten seconds, and at the end of about twenty seconds there was almost an entire subsidence of the commotion. From this instant the recurring disturbances gradually diminished, and at 11:20 A. M. they had entirely ceased. At this time the ice-wagon was directly opposite the observatory.

The waves of disturbance certainly increased in amplitude until 11:18:15 A. M., and gradually diminished after that time. The intervals between the waves appeared to be about 15 seconds, but attention was not withdrawn to the chronometer to be accurate as to this. Prof. Rogers is not quite certain whether there were three or four waves preceding the one having the greatest amplitude. The direction of the waves as indicated by the movement of the spot reflected on the mercury surface, was certainly not due east and west, but rather about 15 degrees from the north and south line; that is, north of east and south of west. On the following day, by arrangement with the driver, an ice wagon was started from about opposite the observatory, to be driven rapidly away. Under these circumstances, only a very slight tremor of the mercury surface was visible, while the cart was traversing a distance of about 750 feet, after which the tremor ceased. The readings of the chronometer were corrected to given Eastern time, as above stated.

Modern Discoveries in Science.

Prof. G. C. Stokes, Secretary of the Royal Society of England, recently delivered a very interesting address before that body, in which he gave an interesting account of the progress of physical science during the past quarter of a century, and in reviewing the results, especially noted that as scientific truth developed, so had men to give up the idea that there was any opposition between the Book of Nature and the Book of Revelation.

He remarked that for the last twenty years or so, one of the most striking advances in science had been made in the application of the spectroscopic, and in the information obtained with regard to the constitution of the heavenly bodies. The discovery that there were in such bodies the particular chemical elements, which were also present in our earth, exalted our idea of the universality of the laws of nature, and there was nothing in that contrary to what he had learned from Revelation.

Entering with some particularity into the composition of the sun, the professor said this gave an idea of an enormous temperature, since iron existed there in the form of vapor. This was wholly inconsistent with the possibility of the existence there of living beings, at all approaching in character the inhabitants of the earth. Are we then to regard this as a waste of material? Might we not rather argue that as in animals, we ascend by greater specialization, some could consider the differentiation of office in different members of the solar system as marks of superiority, and could regard the sun as performing most important functions for that system? In fact, all life on our earth was ultimately derived from solar heat. Referring to the doctrines of conservation of energy and dissipation of energy, he pointed out, at a

length, how the sun, so far as we could see, was not calculated for an eternal duration in the same state, and performing the same functions as now. We must regard the universe on a grand scale, and then there was progress. If we contemplated nothing but periodicity, perhaps we might rest content, and think things would go on forever as at present.

HUMAN ELECTROTYPES.—M. Kergovatz, a chemist of Brest, has proposed a new method of disposing of the human body after death, which he considers preferable in every way to either burial or cremation. His system is an antiseptic one, much simpler and less expensive than the old process of embalming, and is nothing more than a new galvanoplastic application. The body is coated with a conducting substance, such as plumbago, or is bathed with a solution of nitrate of silver, and after decomposition of which, under the influence of sunlight, leaves a finely divided deposit of metallic silver. It is then placed in a bath of copper sulphate, and connected for electrolysis with several cells of a gravity or other battery of constant current. This result is that the body is incased in a skin of copper, which prevents further change or chemical action. If desired, this may be again plated with gold or silver, according to the taste or wealth of the friends of the dead. M. Kergovatz has employed the process eleven times on human subjects, and on many animals, and states that in all cases it was perfectly satisfactory. In spite, however, of his warm recommendation, this idea is repulsive. It seems a mockery to give permanence to the temple where all that once made it valuable is gone.

ARCTIC EXPLORATIONS.—There can be but one opinion among men of science in regard to a certain sort of arctic expedition. A vague "patriotic" impulse to plant the flag of any given country at the pole, taken by itself, is no more entitled to respect than is the motive which prompted the wanderings of "Sergeant Batee" over regions generally accessible. An expedition fitted out for mere glory, without any definite scientific object or well-matured and clearly understood plan officered by men whose courage, enthusiasm and inexperience are their only qualifications, is in no respect to be commended. Such expeditions have had their share of the glory they sought, and have contributed an enormous proportion to the total of arctic disaster. It is to be hoped that there will be no more of them, in spite of the fact that they have also contributed something to the common stock of knowledge. Scientific exploration of the arctic regions will go on. Like other undertakings which depend for the stimulus of war upon national or individual interest and liberality, it will have its periods of activity and inaction. But that the crown of the sphere shall be left to solitude and the auroras, while science with her questions and man with his ambitions coexist upon this planet, is a proposition requiring no refutation.—*Science*.

WHAT AN EDUCATED MAN OUGHT TO KNOW.—According to Ruskin, an educated man ought to know these things: First, where he is—that is to say, what sort of a world he has got into, how large it is, what kind of creatures live in it? Secondly, where is he going—that is to say, what chance or reports are there of any other world besides this, and what seems to be the nature of that world? Thirdly, what had he best do in the circumstances—that is to say, what kind of faculties he possesses, what are the present state and wants of mankind, what is his place in society, and what are the readiest means in his power of obtaining happiness and diffusing it? The man who knows these things, and who has his will so subdued in the learning of them that he is willing to do what he knows he ought, is an educated man; and the man who knows them but is uneducated, though he could talk all the tongues of Babel.

THE MAGNESIUM LIGHT.—Magnesium, says *Nature*, which has more than once been abandoned as a source of light, appears about to be employed again. A Mr. Graetz has succeeded in producing pure magnesium by electrolysis, and at a price much less than that at which it has hitherto been sold. So there are serious thoughts of using it for lighting purposes. The Bremen aluminum and magnesium factory that is working the Graetz process has just offered two prizes for magnesium lamps with clockwork movement; \$125 and \$50 will be awarded to the constructor whose lamp shall be adjudged the best and most practical. The Bremen manufactory reserves to itself the right of working the two systems that are rewarded.

SOME CURIOUS HAILSTONES.—A Minnesota correspondent of the *Scientific American* writes of a hail storm experienced over a narrow district of that State, on September 14th, where the hailstones falling reached a size of 9 to 11 inches in circumference. On being broken open, the interior was like frozen snow, but surrounded by different rings of clear ice, as though they had, in formation, been suspended some time in the upper air, and during this period had passed through clouds of greatly varying temperature.

AN AMALGAM FOR ELECTRIC MACHINES.—Equal parts of zinc and tin filing mixed with sufficient mercury to form a thick paste, and pulverized when they are partly hardened, make an excellent amalgam for electric machines.

Passing Events.

The recent heavy rains all over the coast have, of course, raised the rivers and streams, and filled the ditches, etc. The influence of a good water season is not now so much noticed as in the days when hydraulic mining was permitted.

They have made ten-hour shifts the rule in the Con. Virginia and California mines, on the Comstock, an example set some months since by the leasers; but this is the first time the mine managers have done such a thing. Lack of good ore is given as a reason. The eight-hour shift has been so long a custom on the Comstock that this innovation will scarcely be regarded favorably by miners.

The talk of the hour is the success attained in a number of towns on this coast in getting rid of the Chinese within their limits, by simply giving them notice to leave at a certain date. The President has issued a proclamation concerning the Seattle affair, and United States troops have been placed in readiness to prevent violence. The Chinese thus driven out are mostly coming to this city.

SEVERAL shipments of bullion were made from the Bernice, Nevada, mines during October, aggregating \$9000. The mill is at present running on ore from several mines, which are under the management of G. W. Bothwell.

Utilizing Electricity.

There is a constant tendency to press electricity into service in all directions, and in many cases successful results have been accomplished. It is possible, however, to overdo this. There is something mysterious to most people about electrical action, and in the hands of the charlatan it is an agent which is useful to mystify his dupes. It is so easy to explain results as due to electricity. People do not like to confess their ignorance of electrical action, and take for granted a great deal that is told them concerning its wonders.

Miners and metallurgists are utilizing the agent in many ways already. The miner uses it for firing shots, lighting, transmission of power, underground railways, signaling, etc., while the metallurgist uses it in assaying, in the electrolytic separation of metals, in precipitating fumes from furnaces, in amalgamating, etc.

We have of late described the use of electricity in the Wiswell process for working ores, and in preparing electric amalgam for milling purposes. In another column of this number of the PRESS is a description of Barker's method of utilizing electricity for keeping the pulp agitated while amalgamation is going on. In the Cassell process electricity is called in to assist the metallurgist in another way. A current from a dynamo is made to pass through the finely pulverized ore and salt water revolving in a drum. Chlorine is liberated, and attacking the gold, converts it into the soluble terchloride; this passes through an asbestos cloth filter, and, on reaching the negative pole, the solution is decomposed and the gold deposited in the form of a black powder. The addition of lime prevents iron and other metals from passing into solution. This ingenious invention cannot be said to have gone beyond the experimental stage, and it remains for actual practice, on a large scale, to decide how far it will prove capable of treating refractory gold ores with profit.

It will be seen from these few examples that electricity is being utilized by the mining community, though a good deal of it is yet in the experimental stage. It will not do, however, because one is told that there is "electricity," to believe it is going to cure all the evils and revolutionize everything.

Blasting Appliances.

A good many systems have been tried to avoid the dangers from explosions from fire-damp while blasting in coal mines. Some try to get rid of the flame of powder by a water cartridge inserted upon it, whilst Mr. Clark, with the same object, surrounds the explosive by a compound containing carbonate of soda and other chemicals. Compressed lime cartridges have, in some kinds of coal, proved an efficient, and, of course, safe, substitute for gunpowder, and mechanical appliances may also be used. Another plan is an apparatus like the plug and feathers, except that the two parts corresponding to the feathers are forced open by two wedges drawn together by a right and left-hand screw, instead of by one wedge driven in by a sledge.

In the mining and metallurgical department of the recent Novelties Exhibition in England, there was exhibited a new instantaneous fuse and igniter, the object of which is to fire several holes simultaneously, a matter of importance in blasting out a large central core, when driving a level or sinking a shaft. Hitherto this has been done by electricity, but the new fuse enables the miner to attain his purpose without such aid. The igniter is a tin cylinder, from which proceed, like the arms of an octopus, small lengths of a special kind of fuse which burns instantaneously. One of these is inserted into each hole, and a piece of ordinary fuse serves to convey fire to the igniter. After lighting the ordinary fuse, the miners have plenty of time to retire, and when the fire reaches the igniter it flashes down in an instant to each of the separate charges, and they explode simultaneously, doing more work than if they had been exploded singly.

Another new thing exhibited there, was an ingenious blasting plug to take the place of tamping. It is a hollow cylinder of thick india-rubber, which is placed in the bore-hole after the powder, and swells out when a conical brass plug is screwed into it. As the progress of

tamping is the most dangerous operation in blasting, any attempts to avert the risk overhanging the miner must be welcomed; but it is a question to be decided by practice whether such plugs will last long enough to make them economically available. It will take time to find the plug after a blast, but, on the other hand, no time is taken up in tamping.

Patents.

The Patent Department of the United States is a source of profit, inventors really paying in more than the Government pays out to run the Department. The total receipts last year were \$1,075,798.80, and the expenditures \$970,579.76, leaving a balance of \$155,219.04. There were 35,600 applications for patents, and 20,297 granted and issued. During the year 12,301 patents expired.

It will be interesting to note how many patents were issued by residents of this coast, and the proportion of patents to population. We have compiled the following table to show these results last year:

	Patents and Designs	One to every
Arizona.....	9	4,493
California.....	514	1,682
Colorado.....	110	1,766
Idaho.....	4	8,152
Montana.....	10	3,915
Nevada.....	17	3,602
New Mexico.....	6	19,927
Oregon.....	42	4,161
Utah.....	24	5,395
Washington Territory.....	23	3,265

It will be seen by this that California is a State where the proportion of inventors is large. She is beaten in this respect by very few States. Connecticut last year had one patent for every 694 people in the State; District of Columbia, one for each 558; Massachusetts, one for every 930; New Jersey, one in every 1,184; New York, one in every 1295; Rhode Island, one in every 909, and these are all the States that lead California in this respect.

The 514 patents granted to inventors in this State do not by any means represent the business of California with the Patent Department. There are reissues, trademarks, labels, etc., and more or less miscellaneous business. Moreover the bulk of the patent business of Arizona, Idaho, Montana, Nevada, Oregon, Utah, and Washington is done by San Francisco agents. It is for this reason that the Mining and Scientific Press Patent Agency of Dewey & Co. has been enabled to take the position it has. Being the oldest patent agency here, it has a clientele all over the coast, and attends to the largest proportion of the patent business here. With experienced specification writers and draughtsmen, complete and full records, works of reference, full sets of specifications and drawings of all patents issued, the agency is enabled to conduct the business of inventors in a most satisfactory manner.

When people are applying for patents they should go to a reliable agency of established reputation, where they will be able to consult the records and see for themselves how they stand. There is nothing gained by employing people who profess to be able to get a patent for a few dollars less than others in the business who have all the facilities. Respectable agents make no over-charges, but attend to the clients' business promptly and with intelligence. A little sensible advice from men of experience on patent matters can often save many dollars to inventors. The patent business on this coast has grown to large dimensions, and, as we have shown, the proportion of inventors to the population in this State is very large, and creditable to the future of our industrial advancement.

ABANDONMENT.—The failure to perform the amount of work on a mining claim required by the local mining laws or regulations established and in force in the district where the claim is located, amounts to an abandonment of the claim, and thereupon it may be occupied and appropriated by another. Not to work a mining claim may be a circumstance of some weight, tending to show abandonment; and this abandonment of a claim, resting for validity only upon possession, may be sufficient to defeat the title.

The necessary legal papers for the princely endowment to be made by Senator Stanford for the establishment of a great university at Palo Alto, and the deeding of his ranches in the southern part of the State for the support of the institution have been engrossed and signed. All the details of the gift will shortly be made public.

Electricity and Amalgamation.

Some little time since, some experiments were made in Hungary with a system invented in London, which permits of direct amalgamation by means of electricity, so that gold, silver and copper can be recovered from low-grade ore in a simple way. This plan was found to be a little better than the Desnolles system, at that time in use. The trials were made in this presence of many engineers and experts, and it was found that only two per cent of gold was left in the tailings. The principle was shown in London, also. There clear mercury was put in a china bowl with a lot of oil, and the whole heated until a kind of ointment resulted, and a piece of gold put in, which the mercury, of course, would not touch. The bowl was then filled with water, and the negative wire from a battery was plunged in the mercury and oil, while the positive wire was put in the water. As soon as contact was made the oil began to rise, and in a short time all collected on top of the water, leaving the mercury pure at the bottom.

The machine in which the use of electricity for amalgamating is used is called Barker's electro-amalgamator. It has been put in use in the Australian colonies, and, judging from the reports of the Government officials, seems to be successful there. It has even been put advantageously to work on tailings. It has been patented in this country.

The apparatus does its amalgamating by the combined use of electricity and mercury. A table is used, insulated or not, in which are two or more riffles or batbs containing mercury, at convenient distances from one another, and fitted with ordinary agitators. Over this apron or table the pulp is crushed in the ordinary method. A current of electricity is passed through the apparatus by one or more suitable conductors, in the following manner:

The negative pole (or cathode) of the battery is connected with the mercury in its riffles, and the positive pole (or anode) is introduced into the water immediately above the mercury and sufficiently close to it to cause an energetic action, the electric current being allowed to pass through the water by placing in it at convenient distances, plates or wires of copper, or other good conductors of electricity. The introduction of an electric current into the water, as specified, causes continual agitation of the auriferous material and sand at the surface of the mercury, prevents it from "sickening" in the presence of arsenic, sulphur, oil or other known substances which are deleterious to the action of mercury in amalgamating, and also prevents titaniferous or titanic sand, or other heavy mineral deposits from remaining on the surface—that is to say, the surface of the mercury immediately under and around the copper plates, wires or the like are kept thoroughly bright and capable of amalgamating readily with the gold and silver despite the foreign substances. The conducting plates are made either stationary or movable, and attached to the riffles, taking care, however, that, if revolving or otherwise in motion, the plates or wires shall never come in contact with the mercury.

The machine which was tried before the Government mining officials at Melbourne consists of a common riffle-table, such as would ordinarily be placed next a battery of five bead stamps, the length and width being about the same as the tables now in use. The table has riffles and is covered with electro-plated copper plates, such as those now used on the ordinary riffle-tables. Across each riffle is a bar or band of carbon, which comes down to within a quarter of an inch or so of the surface of the quicksilver in the riffle. There are likewise sliding carbon bars, which, by a mechanical motion, are made to move up and down directly above the surface of the copper plates that are between each riffle, so as to touch the water that flows over the tables, but not to touch the surface of the plates. The negative wires from the battery are placed in the quicksilver and to the copper plate, while the wires from the positive pole are attached to the carbon bar or bands that are placed across the box, thus sending the current through the water into the quicksilver. The official who examined it mixed up some mercury with grease in a dish to test the effect that the electricity had upon it, and although the mercury was so sickened with the grease that it was perfectly useless for amalgamation, in a few minutes after the current was turned

on the effect produced was almost magical: the grease and impurities came boiling out of the mercury, and left it in a pure and bright condition.

New Smelting Furnace.

Three subjects of the Queen of Britain, residing at Melbourne, Victoria, have recently patented in this country a furnace for smelting and reducing metallic ores, especially those which form oxides or compounds that may be reduced by heated charcoal—such as ores of antimony, bismuth, copper, tin and zinc. It consists essentially in a furnace wherein there are a fire chamber, a fine and a reverberatory reducing hearth, and interposed and extending through said flue, but not in internal communication therewith, a series of smelting pots, chambers or crucibles, open at bottom over an independent hearth provided with a tap-hole, and an independent flue connection with the chimney, said crucibles being at top outside the furnaces and provided with a luting cover.

One part of the device shown in the patent drawings (relating to the production of oxides from sulphides, arsenides and other oxidizable ores) consists of a hearth on which the raw ore is treated. When the ore is easily fusible—such as sulphide of antimony—the method of treatment differs from that of ores not readily fused. In the case of sulphide of antimony, the hearths in use usually consist of a solid surface with a tap-hole in some convenient portion for drawing off the fused sulphide, which is then smelted in a crucible or furnace. The hearth is not solid, but has perforations through it which allow the fused sulphide to pass on to a solid bed underneath, when the sulphide is converted into oxide; or, if required for any purpose, may be drawn off as sulphide. When the ores do not fuse readily, the oxide may be formed in any of the ordinary ways now in use.

Another part of the device shows means whereby the oxides may be converted into metal, whether natural or artificial. This is accomplished by smelting them in a furnace so constructed that the draft is downward through the oxide in process of smelting and through the carbonaceous material used in such processes. The furnace is so arranged and constructed that the heat from one fire is utilized for roasting the ore, perfecting the oxidation and producing the metal from the oxide.

PLUMAS COUNTY NOTES.—At Quincy, Plumas county, one of our traveling correspondents finds that, as a rule, miners are not being very well rewarded for their perseverance. Many are still hopeful, however, as evidenced by Mr. J. B. Higgins, who owns the Michigan Hill claim with Mr. Robert Martin—both subscribers of the MINING AND SCIENTIFIC PRESS—who are making substantial preparations for next season's run. They are expending a considerable sum for iron piping for their claim. Our correspondent mentions a natural soda spring that is passed on the road from Crescent Mills, which produces a most excellent natural mineral water. There are others like it in the neighborhood. All the scenery from Crescent Mills to Quincy is well worth a tourist's trip, and at Quincy the Plumas house, our correspondent writes, furnishes accommodations second to none outside of San Francisco. He also sends us word that many kind inquiries are made regarding the publishers of this paper, who are well known wherever he has gone.

The Ontario stockholders are lucky individuals. The regular monthly dividend, No. 112, of 50 cents per share, has just been paid, and also an extra dividend of 50 cents, making a total of \$150,000. For several months past the output of this Utah mine has exceeded the expenses and the dividends, and this extra dividend is declared in order to dispose of part of the surplus on hand. With these two dividends the stockholders will have received a total of \$6,875,000.

A TABULAR statement of the net receipts on ore shipped by the Sierra Grande Mining Company from Lake Valley, N. M., within the year, taken from their annual report, shows that they shipped 16,287 tons of ore, receiving therefor \$523,500. There still remains on the dump 5000 tons of ore.

The Stetefeldt furnace at Bullionville, Nev., will be completed before very long.

The Huntingdon & Koch Process.

The Huntingdon & Koch machine is one intended for amalgamating roasted ore on the same principle as that known as the "Jourdau process." The ore is ground dry, in a bath machine, to a fine powder, and passed through a screen having about 2000 holes to the square inch. The dust is then forced up through a column of mercury in the following manner: There is a hollow tube which forms a vertical shaft having two short, hollow arms near the lower end, which revolves in a column of quicksilver about 18 inches in depth, at a speed of from 250 to 280 revolutions per minute. The arms at the lower end of hollow shaft have openings on the sides on the same principle as the primitive turbine wheel of the very old type. The

where ore passes through into mercury; *k*, vertical and horizontal screen to prevent the rotation of the amalgamating metal; *l*, slits in orifice *h*. The drawing shows a section through the center of the amalgamator.

Since writing the above we have seen in the London Mining World an account of trials with the Huntingdon & Koch process for treating pyrites, made at the metallurgical laboratory of King's College, in the presence of several gentlemen connected with the mining industries. The World says:

"This process, it is ascertained, has been successful in dealing with the ores of Australian mines, and notably with those of Victoria, where it has been pronounced in the Government Blue Book of 1885 'the best amalgamator ever seen in the Colonies, and the only amalgamator capable of treating tailings efficiently

through it was said to give up all the gold that could be amalgamated. No ocular demonstration of this assertion was forthcoming. This amalgamator, 15 inches in diameter and about three feet high, it was stated, will pass one and one-fourth tons per hour, together with the volume of water flowing from the stamps, without diminishing its amalgamating efficiency. One of 20 inches diameter will pass two and one-half tons, and so on, in proportion to their respective areas. With a reduced percentage of water the output of ore would, of course, be greater. The large quantity of ore which these amalgamators can treat is owing to the height and body of the column of mercury through which it passes, together with the principle of distribution employed. The 15-inch machine will take all the pulp from eight heads of stamps direct. The expenditure of power is about two-horse power per machine of this size. The action of the invention is automatic and continuous, one man being able to look after several machines. Another feature is said to be that there is no appreciable loss of mercury; the saving on this head, compared with other systems, alone represents a large revenue. The cost of a machine is about £300. It is put together with great simplicity, and there appears to be nothing about it that is likely to get out of order. The gold is extracted without any additional treatment—chemical, electrical or otherwise. Very little labor is required, and even that employed need only be of the most unskilled kind. The experiments at King's College on this occasion seemed to impress those who were present with the idea that by the Huntingdon & Koch patents a most important step in advance has now been taken; but, we repeat, no results have been announced, although promised—a circumstance which somewhat detracts from the glowing statements made about these processes."

TEN HOUR SHIFTS have been made the rule in the Con. Virginia and California mine, by the proprietary management working the lower levels conforming to what has been the rule in the Jones lease section for months past. The decrease in the quantity and quality of the ore is the cause assigned. In the old upper levels of the mine, under the Jones contract, 10-hour shifts have been the rule for months past. So also in the Gold Hill mines. In Sierra Nevada, Mexican, Union, Ophir, Best & Belcher and Gould & Curry eight-hour shifts rule. In the hot lower levels of the Hale & Norcross and Chollar the miners work six-hour shifts.

NORTH CAROLINA COPPER.—The copper mining interests of the counties of Ashe and Watauga, N. C., have not proved successful. After a loss of about \$1,500,000 at Ore Knob, Ashe county, work has been suspended. Other mines in the same county have likewise ceased to operate. The enterprise at Ore Knob was a joint stock company, owned principally in Baltimore and Philadelphia. The Elk Knob mine is in Watauga county, and has a capital stock of \$500,000, but the price of copper has been so reduced that it will not pay to work the mine, and operations have been suspended.

N. Y. ANTI-MONOPOLY LEAGUE.—A circular shows that this league is still active. It announces the following principles: "We advocate and will support and defend the rights of the many as against privileges for the few. Corporations, the creation of the State, shall be controlled by the State. Labor and capital— allies, not enemies, justice for both." Parties wishing information of this league should address William L. Snyder, Secretary, No. 150 Nassau street, New York.

As the coming winter will undoubtedly be an exceedingly hard one on Wood river, all who are out of employment and have no means of support would do well to seek work elsewhere. The mines have their winter forces on, and are not likely to employ any more men than at present until next spring.—Wood River Times.

A GENERAL convention of the Knights of Labor will be held in this city on the 30th inst. The circular calls for an anti-Chinese and anti-convict labor association by the representative assemblies of the Knights of Labor, trades and labor unions and Grangers' associations.

ABOUT thirty-five miles east of Chelatchie Prairie, on some of the headwaters of the Lewis river, north fork, a party of men are at work on a new mineral belt, which has never been found before this season, says the Vancouver Independent.

The Superintendent of the mint has received instructions from Washington to purchase, on Tuesday of each week, an amount not exceeding 50,000 ounces fine of crude or dore silver bullion for granulating purposes.

THE HUNTINGDON & KOCH AMALGAMATOR.

great velocity at which the shaft and arms revolve draws in the dust, which is fed through the hollow vertical shaft, and the quicksilver, having the greatest density, forces the lighter particles to the top, and retains the gold. Mr. Langtree in his report on Victorian mines, states that this machine has been publicly tested, and over 100 tons of ore put through in competition with the ordinary appliances, at Sandhurst. The results were, according to the nature of the ores, from 11.32 to 18.2 per cent more gold than from batteries, tables, riffles, blankets, etc.

The engraving on this page shows the machine: *a*, is a cast-iron basin filled with mercury; *b*, hollow shaft into which the ore passes from hopper; *c*, a stationary pipe or sleeve; *d*, driving pulley fixed on hollow shaft *b*; *e*, hopper in which ore is placed; *f*, outlet for drawing off mercury and amalgam; *g*, outlets at top of basin where tailings are discharged; *h*, orifice

and economically.' The report adds: 'With ore containing pyrites, a very large percentage of the gold therein is saved. In late workings, the pyrites in tailings showed there was not sufficient gold left to pay for treatment.' This merit of this process may be described in a word. Every particle of ore is brought into contact with the mercury, whereas by other processes much of it is allowed to escape. By the Huntingdon & Koch patents both pyrites and float gold ore can be successfully treated, and little water is required in the process. The advantage of this in remote regions, where it is difficult to obtain an adequate water-supply, must be apparent to all acquainted with even the rudiments of mining work.

"The experiments upon this occasion were conducted upon about half a cwt. of quartz, taken from Moodie's reef in the Transvaal Goldfields. The quartz had first been ground as finely as possible, and was then mixed with water, passed through a hopper, and brought into contact with mercury by means of a revolving tube worked by a pulley. The tube, it was seen, communicated with a cylinder at the bottom containing the mercury, and the ore rising

PRACTICAL HYDRAULICS.*

NUMBER 6.

PRINCIPLES OF HYDRAULICS.

[Written for MINING AND SCIENTIFIC PRESS by P. M. RANDALL.]
[COPYRIGHTED.]

The equation of the parabola, in which x and y are co-ordinates, is:

$$y^2 = 2px; \text{ whence } y = (2p)^{\frac{1}{2}} x^{\frac{1}{2}}. \quad (64)$$

The equation of flow is:

$$dQ = c (2g)^{\frac{1}{2}} (2p)^{\frac{1}{2}} x^{\frac{1}{2}} dx. \quad (65)$$

Integrating (65) between limits $x=0$, and $x=h$; and substituting the values of $(2p)^{\frac{1}{2}} = \frac{b}{h^{\frac{1}{2}}}$, $(2g)^{\frac{1}{2}} = 8.025$.

$$Q = 4.0125 c b h^{\frac{3}{2}}. \quad (66)$$

Let $Q =$ the flow in weir represented by Fig. 12.

$$dQ = c (2g)^{\frac{1}{2}} (2p)^{\frac{1}{2}} h^{\frac{1}{2}} \left(1 - \frac{x}{h}\right)^{\frac{1}{2}} dx. \quad (67)$$

Integrating (67) between limits $x=0$, and $x=h$, and substituting the values of $(2p)^{\frac{1}{2}} = \frac{b}{h^{\frac{1}{2}}}$ and $(2g)^{\frac{1}{2}} = 8.025$,

$$Q = 3.1546 c b h^{\frac{3}{2}}. \quad (68)$$

Assume any ratio, n , to exist between the base b , and the height on head, h ,

$$\text{as } b = nh. \quad (69)$$

$$\text{Then } Q = 3.1549 n h^{\frac{5}{2}}. \quad (70)$$

This formula is adapted to the finding of the flow of water over both shallow and deep weirs. Thus by making n successively equal to 1, 2, 3, 4, 5, 6, 7, etc., the represented flow in (76) becomes correspondingly affected. To accomplish a similar result by the semi-circular weir, would be no easy task, requiring the employment of a very intricate and unwieldy formula or extensive table.

Making in Eq. 70, $n=2$, there results:

$$Q = 6.3092 ch^{\frac{5}{2}}. \quad (71)$$

In this case, $b=2h$, and hence:

Comparing equations (71) and (35), and making $c=.616$,

$$Q = 1.4734 Q. \quad (72)$$

TO FIND, BY TABLE 4, THE FLOW OF WATER OVER A PARABOLIC WEIR, WITH AN OPEN TOP—THE WIDTH BEING EQUAL TO TWICE THE DEPTH OR HEAD.

Rule 21.—Multiply the flow in Table 4 for the head or depth, equal the given head, by 1.4734. See formula (72).

Ex. 32.—In a parabolic weir, with open top, the head is 11 inches, and the width 22 inches. What is the discharge of water through it in cubic feet per second?

Cal. by Table 4—Flow corresponding to head of 11 inches, 2.1696 cubic feet.

Then by Rule 21:

$$2.1696 \times 1.4734 = 3.1967 \text{ cubic feet.—Ans.}$$

COMPARING EQUATIONS (70) AND (35), AND MAKING $C=.616$,

$$Q = .73705 Qn. \quad (73)$$

To find by Table 4 the flow of water over a parabolic weir, with open top—the width being a given number, n times, the head or depth.

Rule 22.—Multiply the flow in Table 4, for the head on depth, equal to the given head, by .73705 times the ratio between the given head and width. See formula (73).

Ex. 33.—In an open parabolic weir, the head being 10 inches, and the width 50 inches—that is, 5 times 10 inches ($n=5$), required the cubic feet flow per second.

Cal.—By Table 4, flow due 10 inches, 1.6713.

By Rule 22.— $1.6713 \times .73705 \times 5 = 6.1592$ cubic feet.—Ans.

Comparing Equations (66) and (35), making $b=nh$, as in (69), and $c=.616$,

$$Q = 9375 Qn. \quad (74)$$

TO FIND THE FLOW OF WATER THROUGH A PARABOLIC WEIR, WHOSE APEX, A, FIG. 11, IS AT THE LEVEL OF STILL WATER.

Rule 23.—Multiply the flow in Table 4, due the head or depth equal to the given head, by .9375 times the ratio, n , between the given head and width.

Ex. 34.—In a parabolic opening or weir, whose apex reaches the surface of still water, the head or depth being 23 inches, and the width 230. inches—that is, 10 times 23 inches ($n=10$), required the flow in cubic feet per second.

Cal.—By Table 4, flow due 23 inches, 13.4089.

By Rule 23, $13.4089 \times .9375 \times 10 = 125.71$ cubic feet.—Ans.

FLOW OF WATER THROUGH A SUBMERGED TRIANGULAR OPENING, HAVING ITS VERTEX BELOW THE BASE.

FIG. 13.

Let, in Fig. 13, BCD represent the opening, in which $b=BD$, the width at top; $h=AE$, head on the top of orifice; $h_1=AC$, head on its bottom; c =coefficient of discharge; $(2g)^{\frac{1}{2}}$ =acceleration of gravity; Q =discharge in cubic feet per second; x =any part of EC, estimated from E; $a=EC$, depth of opening.

$$\text{Then } dQ = c (2g)^{\frac{1}{2}} (h+x)^{\frac{1}{2}} \left(\frac{a-x}{a}\right) dx. \quad (75)$$

Integrating (75) between the limits $x=0$, and $x=h_1-h$,

$$Q = \frac{2c(2g)^{\frac{1}{2}} b}{a} \left\{ \frac{2h^{\frac{5}{2}}}{15} - \left(\frac{h_1}{3} - \frac{h}{5}\right) h^{\frac{3}{2}} \right\} \quad (76)$$

If in (76), we make $h=0$, and $b=2a$, there results:

$$Q = \frac{8}{15} c (2g)^{\frac{1}{2}} h_1^{\frac{5}{2}} \quad (77)$$

Equation (77), derived from the general equation (76), is seen to be identical with equation (35), for the flow of water over a quadrantal weir.

In equation (76), denote the ratio between the head on the bottom and the head on the top of the triangular opening by m ; thus $\frac{h}{h_1} = m$, and substitute the value of $(2g)^{\frac{1}{2}} = 8.025$.

$$Q = 16.05 \frac{cb}{a} \left\{ \frac{2}{15} - \left(\frac{1}{3} - \frac{m}{5}\right) m^{\frac{3}{2}} \right\} h_1^{\frac{5}{2}}. \quad (78)$$

TO FIND THE FLOW OF WATER THROUGH A SUBMERGED TRIANGULAR ORIFICE, HAVING ITS VERTEX ABOVE THE BASE.

Rule 24.—From $\frac{1}{3}$, subtract $\frac{1}{5}$ of the ratio of the given heads or the bottom and top of the orifice, and multiply this difference by the cube of the square root of the same ratio; subtract the product from $\frac{2}{15}$; multiply the remainder by 16.05 times the product of the ratio between the depth and width of the orifice, the fifth power of the square root of the head on the bottom, and the coefficient of discharge.

Ex. 35.—In a submerged triangular orifice, represented by Fig. 13, the head, AC, on the bottom= $h_1=2.25$ feet; the head, AE, on the top= $h=1$ foot; the width, BD= $b=5$ feet; the depth EC= $a=1.25$ feet; and the coefficient of discharge, $c=.616$. What is the flow in cubic feet per second?

Cal. 1st.—By formula (78) and Rule 24, derived therefrom:

$$\text{Ratio of heads, } \frac{h}{h_1} = m = \frac{1}{2.25} = \frac{4}{9};$$

$$\text{Difference } \left(\frac{1}{3} - \frac{m}{5}\right) = \frac{11}{45};$$

$$\text{Cube of square root of ratio, } m^{\frac{3}{2}} = \left(\frac{4}{9}\right)^{\frac{3}{2}} = \frac{8}{27};$$

Product of this difference, and the cube of the square root of the ratio of the given heads,

$$\frac{11}{45} \times \frac{8}{27} = \frac{88}{1215};$$

$$\text{Difference, } \frac{2}{15} - \frac{88}{1215} = \frac{74}{1215};$$

$$Q = 16.05 \times .616 \times \frac{5}{1.25} \times \frac{74}{1215} \times \frac{243}{32} = 18.29 \text{ cubic feet.—Ans.}$$

Cal. 2d.—Assuming that the effective head is the mean of the given heads on the top and bottom of the

orifice, then will the velocity be as per equation (25) or Rule (8)?

$$v = 616 \times 8.025 \left(\frac{h_1+h}{2}\right)^{\frac{1}{2}} = \left(\frac{2.25+1}{2}\right)^{\frac{1}{2}} = 6.3 \text{ feet per second.}$$

Area orifice= $5 \times 1.25 \div 2 = 3.125$ square feet.

Discharge equal to the product of the velocity and the area of the orifice, $Q = 6.3 \times 3.125 = 19.69$ cubic feet per second.

Cal. 3.—Assume that the true head is on the center of gravity of the opening geometrically considered. In a triangle, the center of gravity is at the intersection of right lines drawn from any two angles and bisecting the opposite sides. Its distance, estimated from an angle, is equal to two-thirds the length of the bisecting line; or estimated from the middle of a side, is equal to one-third the length of the bisecting line.

$$\text{In Fig. 13, } AG = h = h_1 = \frac{a}{3} = 1 + \frac{1.25}{3} = 1.4167.$$

By formula (13), modified by coefficient $v=.616=8.025 (1.4167)^{\frac{1}{2}} = 5.8836$ feet per second, area of orifice, $5 \times 1.25 \div 2 = 3.125$ square feet.

Discharge equal to the product of the velocity and the area of orifice, $Q = 5.8836 \times 3.125 = 18.39$ cubic feet per second.

Comparing these results, it is seen that the second is seven and six-tenths per cent (.076) too great, and the third fifty-four one hundredth of one per cent (.0054) too great.

The rule generally adapted is, that "in all cases when the centre of gravity of an orifice lies at least as deep below the fluid surface as the figure is high," the depth h_1 (that is, the depth at the centre of gravity), of this point may be regarded the head of water. This rule may approximate the truth sufficiently close for ordinary practice, but is not to be employed when a high degree of accuracy is required.

FLOW OF WATER THROUGH A SUBMERGED TRIANGULAR ORIFICE HAVING ITS VERTEX ABOVE THE BASE.

FIG. 14.

Let, in Fig. 14, BCD represent the opening, in which $b=BD$, the width at bottom; $h=AC$, head or vertex; $h_1=AE$, head on bottom; $a=EC$, depth of opening; $(2g)^{\frac{1}{2}}$ =acceleration of gravity; c =coefficient of discharge; Q =flow in cubic feet per second; x =any part of $a=EC$, estimated from C:

$$\text{Then } dQ = c \frac{(2g)^{\frac{1}{2}} b}{a} (h+x)^{\frac{1}{2}} x dx. \quad (79)$$

Integrating (79) between the limits $x=0$, and $x=a=h_1-h$,

$$Q = \frac{2c(2g)^{\frac{1}{2}} b}{a} \left\{ \frac{2h^{\frac{5}{2}}}{15} + \left(\frac{h_1}{5} - \frac{h}{3}\right) h^{\frac{3}{2}} \right\} \quad (80)$$

Denote the ratio between the head on the bottom and that on the vertex by m .

$$m = \frac{h}{h_1}; \quad h = mh_1.$$

Substitute the value of h in (80), and the value of $(2g)^{\frac{1}{2}} = 8.025$.

$$Q = 16.05 cb \left\{ \frac{2m^{\frac{5}{2}}}{15} + \left(\frac{1}{5} - \frac{m}{3}\right) m^{\frac{3}{2}} \right\} h_1^{\frac{5}{2}}. \quad (81)$$

If in the general equation (80), we make $h=0$, and $b=2a$, there results:

$$Q = \frac{4}{5} c (2g)^{\frac{1}{2}} h_1^{\frac{5}{2}}, \quad (82)$$

which is identical with formula (48) for the flow of water through a quadrantal weir having its apex at the water's surface.

To find the flow of water through a submerged triangular orifice having its vertex above the base.

Rule 25. From $\frac{1}{5}$ subtract $\frac{1}{3}$ of the ratio of the head on the bottom to that on the apex of the orifice; add this difference to the $\frac{2}{15}$ part of the fifth power of the square root of the same ratio; multiply this sum by 16.05 times the product of the ratio between the depth and width of the orifice, and the fifth power of

ENGINEERING NOTES.

American and English Bridges.

A very pretty fight is in progress in Japan over the question of American vs. English bridges. Early in the year Prof. J. A. Waddell of the University of Tokio published an elaborate work in two volumes for the purpose of pointing out to the civil and mechanical engineers of Japan the superiority of American to English types of bridges, and the mistake of the Japanese in following the practice of the latter. On account of defects which the author points out in detail the author concludes that "the trouble with English bridges, and, consequently, with those of this country (Japan), is that they are designed by railroad engineers, who have not made a special study of bridge designing, and are therefore incompetent to do the work intrusted to them." On the other hand, the author points out in detail his reasons for the assertion: "That the United States leads the world in bridge building is a fact undisputed even in Europe." Prof. Waddell's hook set several British engineers to writing letters to the *Japan Mail*, in which the statement that American engineers now lead the world in designing bridges work is called in question. Prof. Waddell replies in a very pungent letter, and taking up his opponents' arguments answers them in detail. He remarks that actual inspection of English bridge work in Japan shows a quality of workmanship that is even worse than the cheapest highway bridges of America; one case mentioned, a railway bridge, has its bottom chords so warped that "the floor beams bear on both sides of the same," shims of $\frac{1}{2}$ and $\frac{1}{4}$ inch iron are freely used, and there are open joints in the top chord that paint will not hide.—*Age of Steel*.

A NOVEL STEAMBOAT.—A steamboat of novel construction has recently been designed and built by Mr. Emil Adam, of Prague, Austria, and with which astonishing results were obtained. The inventor set out to reduce the resistance of the water as much as possible, and for this purpose constructed the hull of his vessel of two hollow cylinders, which are tapered from the middle toward both ends, whereby a shape resembling that of a cigar was obtained. Each cylinder is provided on its outer surfaces with a screw thread, formed of metal plates riveted on the cylinder, this line of inclination of the thread being about 45° to the longitudinal axis of the cylinder. Annular recesses or breaks are formed in the cylinders at suitable intervals for the bearings supporting the frame of the vessel. The cylinders are rotated by a suitable engine, of any desired construction, on the deck or platform of the vessel. The water in which the cylinders revolve acts as a nut for the screw threads, whereby a rapid motion in either direction is obtained; especially as the frame, decks, etc., are entirely above the surface of the water, and thus offer little or no resistance.

THE LARGEST SEWER IN THE WORLD.—There is being built in Washington City a sewer which is larger by seven feet than any other sewer in the world. Its smallest part is larger than the largest of the sewers in Paris. For over 2000 feet it is a circular sewer of 22 feet in diameter. There is connected with it a sewer 5000 feet, or nearly one mile in length, of 20 feet in diameter. A fully equipped palace car, locomotive and all, could be run through it without difficulty. This enormous sewer is intended to drain the immense watershed lying to the north of the city. Besides that it will carry to the eastern branch of the Potomac all the contents of the smaller system of sewers in the northern part of the city. It will take probably a year to complete the work. The Boundary street sewer, with its connecting systems, will cost when completed over \$700,000. At present the excavation is made by machinery operated by steam-power, which lifts the dirt out and lands it on the completed part of the work by means of a system of cables. The same cables also are used in lowering the bricks and cement to the workmen.

The last spike on the Canadian Pacific Railway was driven on the 5th of October, and the line opened for traffic from the East to the heart of British Columbia. The stations along the north shore of Lake Superior are all named, divisional headquarters have been selected, and preparations made to meet any demand on the company's facilities. Although nominally completed, it is not intended to open the line west of the Siskiwits for traffic until next May. This step is rendered necessary in consequence of the amount of work still to be done in the way of hallasting, erection of water tanks, station buildings and shops. It has also been deemed prudent to study the action of the snow in the Selkirk at least one winter before commencing operations. The terminal arrangements on the Pacific are yet to be provided.

TRAFFIC over the East River bridge has increased something like 20 per cent within the last four months. At times the passengers number over two per second one way. It took two years after the opening of the bridge to roll up the first 25,000,000 passengers. Up to this time the increase of traffic has exceeded expectations.

USEFUL INFORMATION.

THE OCEAN FLEETS OF THE WORLD.—In the following figures are given, first, the sea-going merchant fleets (sailing vessels) of all nations; second, the sea-going steamships of all nations; Great Britain owns 22,800 sea-going vessels, with an average capacity of 500 tons. The United States owns 6600 vessels, with an average capacity of 410 tons. Norway, 4200 vessels, averaging 357 tons. Germany, 3000 vessels, averaging 466 tons. France, 2900 vessels, averaging 380 tons. Italy, 3200 vessels, averaging 312 tons. Russia, 2300 vessels, averaging 260 tons. All nations own 41,700 sea-going vessels, aggregating 23,000,000 tons.

It will thus be seen at a glance how largely England outrivals every other maritime power. She owns one-half of all the ocean sailing marine of the world, within this small fraction of one-twentieth; while her preponderance in the steam marine is even vastly greater. Great Britain owns 4649 sea-going steamships, while all the rest of the world besides own but 2038. We itemize the steam vessels as follows: Great Britain, 4649 steam vessels, averaging 1275 tons; France, 458 steam vessels, averaging 1434 tons; United States, 422 steam vessels, averaging 1424 tons; Germany, 420 steam vessels, averaging 1133 tons; Spain, 282 steam vessels, averaging 1084 tons; Italy, 135 steam vessels, averaging 1230 tons; Holland, 127 steam vessels, averaging 1220 tons; Russia, 194 steam vessels, averaging 768 tons.

PHOTOGRAPHY THEN AND NOW.—It has been said that the sun always gives us true pictures, and so it does if they are not falsified by this hand of the artist. Twenty-five years ago, when photography was quite new, everybody was photographing trus to nature. But of late years science and art have both been improving upon the works of nature, and it is safe to-day to offer a large premium for a true photograph of a human subject. But it is a question whether a man or woman can be found who would be satisfied with such a picture. The man or woman does not live who would be willing to put his or her photograph on view untouched. The honest amateur develops everything, wrinkles and all, and gives you a picture in open and cold unrelief. The professional takes all the pimples and carbuncles and crows' feet off, and you want a couple of dozen. Nobody ever wants more than one of an amateur photograph. If the sun had his own way photographing would die out very fast. Perhaps most people would like to have honest pictures if they were not so blamed homely.

SHAVING RECIPES.—To make shaving cream that can be used without water: Melt 20 lbs. of lard in a steam bath at a temperature of 212 degrees, then let 5 lbs. of caustic potash lye of 36 degrees Baume run in very slowly during constant stirring with a wooden paddle; when the paste becomes thick, 5 lbs. more of lye are added in the same manner. After several hours' stirring, the mixture becomes firm, and is finished. It is then transferred to a mortar, and triturated until the soap becomes perfect ly even throughout, and assumes a pearly appearance. Attar of almonds is the perfume for almond cream, and attar of rose for rose cream. They are dissolved in a little alcohol, and added during trituration.

A recipe for making a shampoo mixture is given as follows: Salts of tartar 4 cunss, pulverized borax 4 ounces, soft water 1 gallon; mix and bottle.

Something to make the hair grow on the face: Take cologne 2 ounces, liquid barts horn 1 drachm, tincture of cantharides 2 drachms, oil rosemary 12 drops. Apply to the face daily and await results.

WALNUT HAIR DYE.—The juice of the walnut rind has been used from time immemorial as a hair dye. Bernschen and Semper have recently communicated to the Berlin Chemical Society a method of preserving it for use in the shape of a hydroglucoside, prepared as follows: The rinds of the ripe nut are digested in sulphuric ether until their coloring matter is extracted. A solution of chromic acid in water is added to the ether solution, and the mixture thoroughly agitated. The ether is then distilled off, and the residue purified by solution, first in hot ether, and afterward in a mixture of chloroform and petroleum ether, from which latter it is obtained in a crystalline form as hydrogen glucoside. This substance colors the hair and skin exactly as does the juice of the fresh rind.—*National Druggist*.

REDUCED POSTAGE and other causes have increased the correspondence of the world. Less than 50 years ago the average of letters received by each person per annum was only three in the United Kingdom, and it is now 37 letters and 4 postal cards. The latest reliable ascertained comparison (for 1882, when the average was 35 in Great Britain) gives the average per head in the United States at 21; Germany, 17; France 16; Italy, 7, and Spain, 5.

CARBOLIC ACID IN PASTE AND GLUE.—The effluvia from decomposing paste and glue is as unwholesome as it is offensive. If, when making the paste or glue, a small quantity of carbolic acid is added, it will keep sweet and free from offensive smells. A few drops added to mucilage or ink prevents mould. In white-

washing the cellar and dairy, if an ounce of carbolic acid is added to each gallon of wash, it will prevent mould and also the disagreeable taints often perceived in meats and milk from damp apartments. Another great advantage in the use of carbolic acid in paste for wall paper and in whitewash is that it will drive away cockroaches and other insect pests. The cheapest and best form of carbolic acid is the crystals, which dissolve in water or liquefy at an excess of temperatures.

NON-POISONOUS VEGETABLE FLY PAPER.—It can be made as follows: Powdered black pepper is mixed with syrup to a thin paste, which is spread by means of a broad brush upon coarse blotting paper. Common brown syrup will answer, but syrup made from sugar is preferable, as it dries quicker. For use, a piece of this paper is laid upon a plate and dampened with water. The paper may also be made directly at the mill by adding sugar to the pulp, and afterwards $\frac{1}{2}$ to $\frac{1}{4}$ of powdered black pepper, and rapidly working it into a porous absorbent paper.

TEST FOR WATERED MILK.—A German test for watered milk consists in dipping a well-polished knitting needle into a deep vessel of milk, and then immediately withdrawing it in an upright position. If the milk is pure, a drop of the fluid will hang to the needle; but the addition of even a small proportion of water will prevent the adhesion of the drop.

TO REMOVE IRON STAINS FROM MARBLE.—Take hutter of antimony, 1 ounce; oxalic acid, 1 ounce; dissolve them in one pint of water, add flour, and bring the composition to a proper consistency. Then lay it evenly on the stained part with a brush, and after it has remained for a few days, wash it off and repeat the process if the stain is not quite removed.

MUMMY WHEAT.—The story of Egyptian mummy wheat having germinated has never been confirmed and is not credited by any one who is warranted by knowledge and experience in such matters to give an opinion. Innumerable attempts to stimulate mummy wheat into vitality have each and all failed.

TOO LARGE BELTS are often used on emery wheels. A belt half as wide as the face of the wheel is large enough. The belt should be loose enough to slip if the wheel is unduly crowded.

VARIETY IN STOVES.—Over 300 styles of stoves are now in actual use and the number is constantly increasing. There are nearly 100 kinds of fire-places heaters, differing from one another mainly as regards the grate.

CUTTING INDIA-RUBBER.—When it becomes necessary to trim a piece of rubber, it will be found that the knife will cut much more readily if dipped in water.

LAWN MOWERS.—The United States produces nearly 50,000 lawn mowers annually, and exports to every civilized country on the globe.

GOOD HEALTH.

Sleep Mechanically Considered.

Whether sleep can in any way be compelled, when the state of mind and body is opposed to it, is a question which we are inclined to answer in the negative. All the devices which have been employed or proposed, such as counting, repeating the multiplication table, reciting passages of familiar literature and the like, are no doubt frequently effective in hastening sleep which would have come more tardily of its own accord; but if the stomach, or heart, or brain, is in a morbidly active condition, such as will not allow unconsciousness to steal upon the system, we doubt if any artificial means will bring about that result. A writer on this subject declares, and we believe truly, that sleep is prevented by an excess of blood in the brain. His remedy is to pump the blood back from the brain by a peculiar method of breathing, for which directions are given as follows: Having assumed the usual posture of repose, inhale and exhale slowly and steadily long breaths, devoting the whole attention to making the inhalations and exhalations exactly the same length. The length should be much greater than that of ordinary breathing, although not sufficient to disturb the circulation by working the lungs to their utmost capacity. In support of this theory reference is made to the feeling of faintness produced by filling the lungs with all the air they will hold and then expelling it, repeating the operation rapidly three or four times. The resulting faintness is attributed to the withdrawal of blood from the brain, and the same effect, substantially, follows any sudden and extreme emotion. So violent a disturbance of the system, however, is not advised for the purpose here sought, but a steady and gradual diversion of the blood from the brain to the lungs and body; and it is confidently asserted that insomnia can be overcome in this way by a resolute and persevering effort.

We believe it will be found true in nearly every instance of sleeplessness, where no actual pain, mental disquiet or other apparent cause exists, that the action of the heart is very rapid and that until it abates sleep will be sought in vain. When a person lies down, the pulse

should within a reasonable time, say, not more than a quarter of an hour, show a reduction of about 10 beats per minute. If in the waking hours it is 80, it should, when one goes to bed, fall to 65 or 70, and sleep will almost certainly follow. But if the heart continues to pound away at the rate of 80 or 90 strokes per minute, there will be no healthy sleep, let the pillows be never so carefully arranged and the conditions of temperature light, exclusion of sound, and so on, the very best imaginable.

How to regulate the system so that the heart will abate its activity at the right time is a question the settlement of which will usually solve the problem of sleeplessness also. Temperance and discrimination in eating and drinking will go far toward removing the difficulty. A due amount of fresh air and exercise is also essential; but violent and exhausting exercise, taken without interest or enjoyment, will often do more harm than good. There are some physical needs which can be supplied at will, by mechanical appliances; but sleep is not one of them. The body may be warmed or cooled, hunger and thirst may be allayed, and some of the functions of the system may be stimulated or checked, to a degree which with some persons almost amounts to artificial control. But sound and satisfying sleep is conditioned upon the general health. To bring it about, one must begin at this beginning; and the work can not be abbreviated, nor the result attained by any patent device which sets the laws of physiology at defiance.—*Mechanical News*.

It Pays Doctors to Cure.

"Do doctors ever practice on their patients?" The above question was asked of a prominent physician. "The number of physicians of sense and reputation," he replied, "who experiment on their patients is quite small. Indeed, I do not know such a practitioner. There is a very erroneous impression among the middle and lower classes of persons on this point. Nothing is more common than to hear some one say, 'Why, I wouldn't think of going to a doctor. When they once get hold of you they'll never let go.' No general statement could be further from the truth. It is to the best interests of a physician to cure the one upon whom he is in attendance, because every cure he effects increases the confidence reposed in him. Almost every day some new disease or some hitherto unknown manifestation of disease is developed in practice, and it is not surprising, therefore, that even the best equipped and most experienced doctor is compelled to occasionally grope around in the *materia medica* before he finds the proper remedy. But the suspicion of the desire for experimenting is so uppermost in the mind of the average patient that it would be difficult to impose upon him, even if it was so desired."

"Do you think that medicine will eventually be able to successfully cope with every kind of disease?"

"I am not at all certain about that. But I would not put myself on record as denying that such a time may come. The practice of medicine has undergone marvellous revolutions since its establishment. Other equally wonderful revolutions are to come. While I believe that some methods will ultimately be discovered for arresting the progress of every disease, no matter how mortal as now considered, I do not put much confidence in the theory entertained in some quarters that anything can ever be done to replace a part or organ of the human body, which has been actually deadened, destroyed or obliterated. For instance, it will not be possible to restore to vitality a lung vitiated by consumption, or to supply a new gizzard in place of one consumed by a malady. But if such things are within the realm of the possible, then there is no doubt that human life can be indefinitely prolonged."

A MUSTARD SPONGE.—In referring to a sponge as a carrier of poultices, Dr. Richardson considers that it makes the best of mustard carriers. Mix the mustard in a basin with water until the mass is smooth and of even consistency. Then take the soft mass all up with a clean sponge, lay the sponge in the center of a white handkerchief, tie up the corners neatly, and apply the smooth, convex surface to the skin. This mustard sponge warmed again by the fire and slightly moistened, can be applied three or four times, is good for several hours, and saves the trouble of making a new poultice during the weariness of night watching. The sponge can afterward easily be washed clean in warm water.

BUNIONS are exceedingly troublesome and painful. They usually result from pressure and irritation by friction. This frequently causes a permanent enlargement of the joint, which it is difficult if not impossible to remove. The treatment for corns applies to bunions for removing the soreness; but in consequence of the greater extension of the disease, the cure is more tedious. When a bunion is forming, it may be stopped by poulticing and carefully opening it with a lancet. Gezow's corn cure consists of: Salicylic acid, 30 grains; Ext. Cantharis indica, 10 grains; collodion, $\frac{1}{2}$ ounce, mix.

INOCULATION FOR HYDROPHOBIA.—The telegraph informs us that at the meeting of the Paris Academy of Sciences, held Oct. 27th, M. Pasteur furnished proof of his theory that inoculation was easily practicable, and had been successful in preventing hydrophobia.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

KENNEDY.—Amador Ledger, Nov. 7: An agreement has been recorded between the Kennedy Mining Company and F. Reichling; the company agreeing to deed the mining property for the sum of \$100,000, to be paid one half in nine months, the balance in 12 months; the party of the second part to have the privilege of extracting and working ores in the meantime; if the purchase money is not paid at the expiration of the time stated the agreement to be void, and all improvements placed upon the mine are to become the property of the company.

MISCELLANEOUS.—We were shown on Saturday a specimen of ore taken from the New York mine, west of Jackson. It is of a dark-colored quartz, containing a quantity of black metal, similar in appearance to that met with in the Nevills mine, but not so heavy. No gold is visible to the naked eye; but Mr. Anderson says it shows free gold in considerable quantity on being roasted. It carries also a heavy percentage of sulphurets, but of what quality we are unable to say. A quantity of the rock has been sent to San Francisco for treatment. W. Boxall has commenced running a prospect tunnel into the east side of Matley's hill.

El Dorado.

GRIZZLY FLAT.—Cor. El Dorado Co. Republican, Nov. 5: The Melton mine during the last few days have struck in their winz; a vein of ore 4 feet in width that excels anything in richness that I have seen in this vicinity. J. M. Oxley is driving his tunnel in the divide between Middle Creek and the little north fork with prospects beyond what he expected. So encouraging is the present showing that he is now constructing a ditch several miles in length from Middle Creek for the purpose of washing drift dirt. Jo Myers is preparing to run a tunnel near the head of Barney Ravine joining Oxley's claim. Kendall & Russell are driving their tunnel into the Hill near Dogtown and expect in a few weeks to strike a channel of rich gravel.

Humboldt.

HYDRAULICKING ON THE KLAMATH.—Humboldt Standard, Nov. 4: Mr. A. Jacobs, who has during the past year been engaged in prospecting the gravel deposits along the Klamath river with a view to interesting capital in working the same for gold by the hydraulic process, returned on the Chester. He is accompanied by Dr. Star and Mr. Frank Perkins, who will operate under the name of Perkins & Co. These gentlemen bring with them a complete outfit for hydraulic work. They expect to put in a ditch and thoroughly prospect the ground about 22 miles above the mouth of the Klamath. Their principal work will be done on Blue creek, where the best gravel is found. Mr. Perkins says they expect to spend the most of the winter in prospecting and getting on water, preparatory to active work by spring. They will have their apparatus and winter supply of provisions conveyed to the Klamath by pack trains from Arcata. We learn from these gentlemen that there is considerable inquiry among hydraulic miners with reference to the water facilities and prospects of the gold bearing deposits along the Klamath and they think there will be many persons anxious to invest in this gold field upon the least encouraging outlook. The "stickens trouble" is turning attention in this direction, and they expect to see active hydraulicizing inaugurated on the Klamath at an early date.

Inyo.

PANAMINT.—Inyo Independent, Nov. 7: A great deal of assessment work will be done during the next month. The re-opening of the Panamint mines is already infusing a little life into some old claims in that region, and a good deal of prospecting and assessment work will be done there from this time forward. The Jacobs Wonder mine produced large amounts of ore formerly, and still contains plenty more that will be worked when milling facilities can be had.

PINE MOUNTAIN.—Inyo Register, Nov. 6: Mr. S. P. Roberts was in town, a day or two since, his visit being for the purpose of obtaining a pack train to pack out about a carload of the fine silver-lead ores he digs out at Pine Mountain, and which lot, as others that have preceded it, is to go to the Selby Works at Oakland. Roberts has spent seven years on his mines at Pine Mountain, much of the time entirely alone, always firm in the faith, and never more so than at this moment, that there was a fortune in store for him in those mines whenever it was in his power to properly work them and reduce the ores on the ground. The bulk of ores, running about 40 ounces in silver, are especially suitable for concentrating. The higher grades have always paid quite well for shipping, although at the very outset, they have to meet the heavy expense of packing and hauling some 17 miles to the railroad.

Kerr.

KRAMER ITEMS.—Calico Print, Nov. 7: Operations have commenced on some of the gold mines at Kramer. Mr. Kilgore has sold to Col. Hewitt, of Los Angeles, Division Superintendent of the Southern Pacific, a one-third interest in the Tip Top mine and a one-third interest in the Keystone, and also a one-third interest in the Tip Top to Mr. Campbell. The Tip Top is down 50 feet and the Keystone 25 feet, both showing up well. Mr. Fancher, of Los Angeles, recently bought an undeveloped claim of Mr. Kilgore and now has three men at work on the same. Jesse Umls is working some mines on shares with Mr. Kilgore. The Koffman Bros., now in Ventura county, will return shortly with a complete outfit and resume sinking on the Coffman mine, which is down 50 feet, and looks well. Mr. McAlleney writes from Oregon that he will return soon to work his mines in Kramer. While up north he visited Trinidad, New River and other camps and declares that so far he has not seen any prospects equal to those of Kramer. The prospects of Kramer are good and it is confidently expected that considerable developments will be made there during the coming year.

Mono.

GOLD LEDGE.—Inyo Register, Nov. 7: A friend, lately down from Mono Lake, describes a gold ledge located about two and a half miles west of the lake,

and about 17 miles from Bodie, as follows: It is known as the Grover Cleveland, and adjoins another location called the Levenfelt. A joint tunnel, but on the Cleveland ground, in a length of over 400 feet, taps the ledge at a vertical depth of 200 feet, and cuts it from wall to wall 60 measured feet, every inch in ore, all about alike in appearance and value. Carefully sampled to determine its probable working value, the assays gave an average of a little over \$11 per ton. Heretofore ores running no higher than that have not been considered of any avail on this side of the mountains, but the time is at hand when such immense ledges of low grade ore are being particularly sought after by capitalists, and for that reason, we wish to call attention to this. A few hundred dollars expended in an actual working test of the ores now exposed is all that is needed to very likely show up a most valuable property. There are about 300 tons of ore now on the dump. Near by are placer diggings that are being regularly worked to fair pay, and the locality is easy of access.

Nevada.

INTO THE OLD CHANNEL.—Grass Valley Union: The superintendent of the Centennial gravel mine, Washington township reports to the company as follows: After passing through the stratum of blue clay and sand, and a streak of fine gravel about four inches thick, of white quartz, well water-worn, four feet below that I have struck old wood that can be cut with a knife, all going to prove an old channel. The best posted gravel miners in this section agree that this shaft is going down directly into an old channel, and that the good gravel should be near by. I am working all the men I can, and pushing the work as rapidly as possible.

MINING NOTES.—The Crown Point mill is running steadily on good paying ore. The new water wheel for the Horseshoe mine is completed and ready for work. The sinking of the Orleans shaft, on the new 100 foot contract is making good progress. Upon the completion of the contract drifting for a new level will be started. The utmost confidence is expressed by those who are best informed on the subject that the Allison Ranch mine will be taken by the French company before the expiration of the term of the bond they have on the property. A crushing from the Boston mine, made this week, gave a yield of over \$30 per load for 36 loads.

ANOTHER RICH STRIKE.—Transcript, Nov. 4: F. Johnston, of North Bloomfield, and A. M. George discovered a big gold bearing quartz ledge about a month ago on Filmore hill, between Wolf creek and the Middle Yuba, a short distance above Moore's Flat. It is a north and south vein and dips east. The owners have already worked into the ledge about 18 feet and have not yet reached the foot or hanging wall, which shows that the vein is an unusually large one. The ledge prospects rich, and at a distance of 700 feet down the hill from where the ledge was discovered the prospect is equally as good. The finders of this mammoth ledge are poor men, and no doubt it is a good opportunity for a company of means to get hold of a good property.

Placer.

IOWA HILL INKLINGS.—Cor. Placer Argus, Nov. 7: A casual mention of some of the work that is going on here and near here will show to the outside world that mining in this vicinity, instead of being a thing of the past, is at this time just in its infancy. The Golden Gate mine at Damascus, never looked so well nor paid so handsomely as it has done during the past year, with every proof of a continuation. It is expected that within a few days this mine will change hands to a French syndicate who have held a bond on the mine for several months past. The Colfax Company whose claim is located some three miles further down the ridge, on the American river side, are at work at present raising an air shaft. When they have completed this work, it is understood that the company will push their main tunnel ahead, with reasonable expectations of striking the Damascus channel. McIntyre is opening a claim a little further down the ridge. He has a tunnel recently driven in some 300 or 400 feet and has struck blue gravel and a splendid prospect. He thinks he will soon be into the Damascus lead. Willis Gould is still driving ahead. He is getting some very good pay, but he works only a small crew. Willis believes in working it slow and making it last. The Watt Bros. a mile below Willis Gould and near Monona Flat, still continue to take out good pay. This is a good mine, and if worked with a larger force of men, would compare dividends favorably with most of the best mines in the county. But the boys only work four or five men besides themselves. Some good looking gravel is being taken out of the Sucker Flat mine, but unfortunately they have no water to wash their dirt for the present, consequently it is impossible to tell just what they are taking out in the way of pay. There is no question but the company have some splendid ground to work whenever they get ready and feel disposed to work it. But at present, for some reason, they seem to prefer to prospect their mine for further developments. The Anglo-American Company have started work in their old tunnel, which is in some 800 or 900 feet. They propose to push it ahead until they strike the main channel further back in the ridge. The Golden Gate Co. are taking out some fine looking nuggets. They have crossed and driven gangways up both rims of the channel some 400 feet, but as yet have done no breasting. The pay channel is thoroughly defined, with high rim-rock on each side. Judging from the pay that is being taken out running the gangways, this mine bids fair to surpass her early day yield many times over, and it is authentically stated that the front ground produced several hundred thousand dollars, and from present outlook is destined soon again to be one of the banner mines of the county.

Shasta.

IGO ITEMS.—Cor. Shasta Courier, Nov. 7: Abbott Hubbard & Co. have out about 20 tons of ore, and have started their amstra to grinding the same. E. L. Ballou is running his amstra on Manzanita ore. J. Woodfield has out a run of good ore. J. Hollister also is taking out fair ore. J. P. Wright is taking out ore, and expects to start his amstra soon. Robinson & Co. are working on the Central, and will start up as soon as water permits. Robinson & Cooper are still taking good silver ore from their Chico ledge. F. and H. Shirland are taking out some good ore also. The Chicago folks are waiting for water to start the mill.

NOTES.—Siasta Co. Democrat, Nov. 4: Judge Bell & Co. re-opened their French gulch mine with a view of putting a mill on it. Last week Peter

Scheerer sold \$1100 worth of land adjoining Distlehorst's old reservoir west of town. Merithew & Co. at Lower Springs have started up their mill but cannot run regularly on account of the scarcity of water. Tom Green was in town yesterday morning and shipped another seven-pound chunk of amalgamated gold, the clean up from another week's run. Clark & Co.'s mill on the old Harrison mine at Quartz Hill is now running night and day. sufficient water having been obtained in the new working shaft. Theodore Popejoy of Copper City was in town a few days ago and reports the old camp lively. He says preparations are being made to work three placer claims in that district the coming winter, owning one himself. A. C. Ellis and Wm. Murray have bonded the mining property on Flat creek formerly owned by Dent Young and will commence work on the same immediately. There is little doubt but they will soon take out good rock—enough to keep their mill at work. An old California miner named Becker, who has mined all over the Pacific Coast, last week struck what he believes to be a rich mine about one and a half miles west of Centerville near Clear creek. It is an immense deposit, claimed to resemble greatly the rich tellurium ore in the Salt creek mine belonging to Scheerer and Ratler. It is certain that some of the ore carries free gold for we panned it out. Becker has a good claim in New River and one on the Klamath in Siskiyou county also, which he discovered the past summer.

Sierra.

CLEAN UP.—Mt. Messenger, Nov. 7: The Bald Mountain Extension Co. cleaned up nearly 123 ounces for four days' work, \$30 per load. The company had seventy-two names on the pay-roll last month. Since the new pump started the air in the mine has been good. Next week the work of taking out gravel will be again temporarily suspended to put in about 2000 feet of new steel track—T rail, taking perhaps ten days. Then the mine will be in thorough working order for the winter, supplies to last until next July having been laid in. The water at the Extension shaft is 120 feet below the top. It takes about three and one-half cords of wood per day to raise a little over 20 inches of water. Wm. Fore has been running a tunnel on his claim down Rock creek during the past summer. South Fork company have their tunnel in 32 feet, and will resume work on it as soon as their blacksmith shop is finished. The course of the tunnel will be through the Oregon and Live Yankee ground to the South Fork ground. The Oregon and Live Yankee claims have been purchased by the South Fork Company. Pay gravel is expected about 800 feet ahead.

Tuolumne.

GOLD.—Tuolumne Independent, Nov. 7: The Buchanan mine is looking fine. Rock is being taken out at the 500-foot level, which is sprinkled with chunks of free gold. The same character of rock is also found in the 400-foot level. It was expected that the mill would be ready to start this week.

CLEAN UP.—Union Democrat, Nov. 7: They cleaned up at the Lamphier mill last Sunday, after a nine days' run. The rock paid handsomely, and there is enough in sight to keep the mill going for some months. A drift is being run from the main shaft to tap the south chute on the 217 foot level, which is expected to open up a considerable extent of new pay ground.

Trinity.

DEADWOOD.—Cor. Trinity Journal, Nov. 7: All the mines look prosperous and every quartz mill is turning out its usual amount of gold. Minear & Co. are doing good work while everything looks prosperous. Everything looks lively around the Black Bear mine and from all appearances it has the old-time prosperity. Wm. Blagrove still holds his own. Some of the ore already crushed yielded about 100¢ per ton. Westlake & Cosgrove are hauling their quartz to be crushed in the Black Bear mill, and will soon hear of a good clean-up. Bothby & Hendricks are doing well, and this winter will make the amstra turn out some bullion for them.

NEW RIVER.—Humboldt Standard, Nov. 6: Jno. McCulloch, who went to New River a week ago yesterday, returned Saturday night. He says there is nothing of great importance to report. The Toughnut, Hardtack and Ridgway mines are running. The lack of water is the greatest drawback and all are anxiously waiting for the winter rains to set in. When they begin, a number of amstras will be started. Mr. McCulloch says New River City doesn't seem to him to be so dull as on his previous visit. There is plenty of work for everybody and few idle men are seen.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Enterprise, Nov. 7: On the 3000 level the main lateral drift north has made a few feet further progress north, showing no material change, and the water is getting pretty well drained out of the crosscut west. Work will be resumed there shortly. On the 3100 level the main lateral drift north has been advanced about 40 feet, making a total length north, beyond the winze station, of about 75 feet. Face in very favorable vein material, with streaks and bunches of pay ore. It is very dry, no water being encountered in this drift thus far. Crosscut No. 2, on this level, has been pushed at a very lively rate through a strong, solid vein of mineralized quartz. It is in about 120 feet, and no water met with as yet. The indications continue favorable for the finding of a large, paying ore body sooner or later.

CHOLLAR.—The main lateral drift south on the 3100 level is in about 260 feet from the switch where it departs from the Combination west drift and continues following along the west side of the ore vein, keeping in the west country rock, which is dry and favorable, allowing of excellent progress. The ore vein, which lies all to the east, is demonstrated to be over 60 feet wide, all solid quartz, and carrying mineral enough to entitle it to be designated as low grade ore. No crosscutting is intended at present, and will not be while such good advancement can be made toward the Potosi line. There is every indication, however, that a good concentration of ore will be eventually found in that section of the vein.

CROWN POINT.—The repairs to the hoisting machinery being completed, a force of about 140 miners were put to work in this mine and the Belcher the first of the week, and a few more have been added from day to day as required. Ore enough is thus

being extracted to keep about half the stamps of the Mexican, Vivian and Santiago mills running, and as soon as the Carson river raises sufficiently to allow the remaining stamps to run, the ore yield and the mining force will be correspondingly increased. Some work is being done on the 1700 level, with a view to breasting out ore at that point in conjunction with similar work and explorations on the 1700 level of the Belcher, Kentuck and Yellow Jacket.

ORE SHIPMENTS.—Eureka Sentinel, Nov. 7: During the week ending yesterday ore shipments were made from the mines of the district to the two reduction works in town as follows: to the Richmond—Republic mine, 15 tons; Mimbres, 10; Whippoorwill, 48; Bowman, 14; Silver Lick, 39; Lord Byron, 7; Hoosac, 15; Dunderberg, 15; Geddes and Bertrand, 21; Eureka Star, 3; Prospect Mountain Tunnel, 5; and Frazier and Molino, 30. To the Eureka Company—Paul mine, 3 tons; Frazier & Molino, 14; Marguerita, 4½; California 32; Queen, 1½, and Silver Gate 1.

OPHIR.—As stated in last week's report, the main west drift on the 400 level from the Mexican shaft is being steadily pushed westward through the vein matter, not having obtained proximity to the west wall as yet. It has a considerable distance to go yet before reaching that point. The lateral drift south, starting from this main west drift, is running in a very favorable formation, allowing of excellent progress, and is already in over 100 feet, cutting occasional streaks and spots of ore. Upraising above this level will soon be commenced after the good ore known to overlie it as high as the 250 level.

YELLOW JACKET.—The usual amount of ore is being extracted from this mine to keep the Brunswick mill steadily running, about 170 tons being extracted daily. Most of this is being taken out without assorting, just as it is found. This is done by way of experiment, in order to ascertain the actual average yield and value, consequently less men are needed, and about 70 were drafted from the mining force on the first of the month. The drift from the Crown Point through the Kentuck ground, to explore and develop the value of this mine on the 1700 level, is making good progress, considering the intense heat and difficulty of supplying good air.

ALTA.—The main west drift or crosscut on the 700 level has been making unusually good progress the last two weeks, the ground being softer and more favorable, on account of its advance now being into the west ore body development sought for. The face of the drift is in low grade ore, but too low for working, but improves with further advancement, and a week or two more of exploration at this point will tell the story.

CON. CALIFORNIA AND VIRGINIA.—The 1750 continues its good regular yield of over 100 tons per day, extracted on company account, assaying about \$19 per ton. This is shipped to the Morgan mill on the Carson river for reduction. Some 50 or 60 tons per day are being extracted from the Jones lease section, above the 1550 level, and shipped to the Eureka mill, on the Carson river for reduction.

SIERRA NEVADA.—On the 520 level the lateral drift started north from the west crosscut is now in about 200 feet, showing no particular change of importance to report. Considerable repairing to the main lateral drift has had to be done.

BEST AND BELCHER.—On the 1000 level the lateral drift south, started from crosscut No. 2 about 250 feet west of the main north lateral drift, is now in about 80 feet, following the strong vein of mineralized quartz it was intended to explore.

MEXICAN.—The middle crosscut on the 500 level continues in very promising vein matter—decomposed quartz, vein porphyry and heavy clay. It is now over 500 feet in length.

KENTUCK.—The usual amount of ore continues to be extracted from the old upper workings, keeping the Rock Point mill well supplied and steadily running.

UNION CONSOLIDATED.—On the 500 level the crosscut east, 100 feet south of the Sierra Nevada south line, is in over 200 feet. Material, vein porphyry, clay and quartz.

GOULD AND CURRY.—The crosscut west on the 1000 level is in 650 feet. No change of importance to report. Material, soft vein porphyry, clay and decomposed quartz.

Columbia District.

MOUNT DIABLO.—Candelaria True Fissure, Nov. 7: We are cutting out the station for the 7th level from the incline. On the sixth level the east drift has advanced 11 feet, and the west drift has been driven 18 feet during the week. The upraise from the east drift on the second level shows a bunch of \$95 ore that looks promising. The east drift from the south crosscut in the Mount Diablo adit is in 62 feet.

AJAX.—This mine is located on Potosi Hill. Messrs. Hastie and Davey have the incline down 100 feet, with about four inches of \$150 ore in the bottom. The east drift is in about seventy feet and the west drift about fifty. Both are looking well.

BLACKBIRD.—William Dunlap and James Colligan have leased this mine and are doing well. They shipped nine tons of ore to Selby & Co. during the week, and are taking out another shipment.

SILVER BOY.—Johnny Leidy and his father are working away at their claim, and the prospects warrant them in believing that they will soon uncover a bonanza.

POTOSI.—The lessees are jubilant over their good luck. The mine is panning out well.

NEW ENGLAND.—The lessees are making excellent progress. Jimmy Davis is working his claim with encouraging prospects. Considerable prospecting is being done in the foothills about Columbus. Kent & Co. are still shipping their regular amount of ore to Selby & Co.

El Dorado District.

GRAND VICTORY.—Placerville Observer, Nov. 7: The Grand Victory mine, after being shut down for a period of one month, resumed operations on the 6th inst. During this period the mill underwent many radical changes. The old Blanket concentrators, through which, probably, one-half of the gold was allowed to escape, were substituted for the more modern and gold saving Canvas concentrators. The motive power was also greatly improved by the introduction of a Turbine wheel, manufactured at the Placerville foundry, which is sufficient guarantee. As the management under-

went a parallel change, we may properly expect "Grand Victory" news in the future.

Hawthorne District.

THE NEVADA.—Walker Lake *Bulletin*, Nov. 4: The Nevada mine in Hawthorne District, owned by Wm. Adams, is creating considerable excitement. The tunnel is in 100 feet on the ledge with a winze sunk 60 feet from the mouth of the tunnel. The winze is down 30 feet from the tunnel with a six-foot ledge at the bottom, improving as it goes down. The rock averages \$50 per ton.

Jackson District.

MILL.—*Silver State*, Nov. 4: Dan L. E. Barron, the discoverer of Jackson District is in town. He is an indefatigable prospector, well posted in mineralogy and geology and knows good ore when he sees it. He discovered the Pennsylvania mine in the Jackson mountains, which is now partially developed by tunnels and shafts. One of the tunnels is run on the lead a distance of 53 feet, and at the face the lead carries a foot of ore that averages \$150 per ton, and from 8 to 12 inches of ore that averages \$30 per ton. There is a shaft 40 feet deep on the vein, in which the lead is strong and the ore good. John Carroll has agreed to put a 10-stamp mill on the mine for an interest in the property, and they expect to have the mill running this winter. Mr. L. E. Barron says that other good prospects have been found in Jackson district, but they are yet undeveloped, and on the other side of the mountain from where the Pennsylvania is situated there are extensive copper leads, which will doubtless be worked when copper becomes more valuable.

Santa Fe District.

PROSPECTING.—*Inyo Independent*, Nov. 7: There is a good deal of prospecting going on in the Santa Fe district, east of Luning. Last Wednesday F. L. Perkins, a mining expert from San Francisco, came down on the train to Luning to examine a mine out near Finger rock, in the interest of San Francisco parties.

Tuscarora District.

GRAND PRIZE.—*Times-Review*, Nov. 7: Have commenced drifting north on the ledge in the 300 level—it is in 18 feet. This is about all the work that has been done in the mine this week, as the engine and other machinery is being repaired. It will be all ready to run again to-morrow—when work will be resumed in the mine.

ARIZONA.

MINING ITEMS.—Prescott *Courier*: Ryland's Southern Belle is opened by a 40-foot shaft, in which the quartz is 6 ft thick. He recently worked 6 tons of rock in an arastra, and it paid at the rate of \$50 per ton, gold. Frank is now near Wickenburg, doing assessment work on a very rich silver ledge. Jacob Henkle, who has just returned to Prescott from the Bradshaw mountains, 45 miles south of Prescott, tells us that considerable rain, hail and snow came down there recently. He visited John Luke's mine and was shown a great many tons of rich silver ore. The Rapid Transit mine is proving to be one of the best mines in a district that boasts of the Cougar, Eclipse, Tiger and Gray Eagle. Del Pasco mill people are praying for a supply of water to run the mill and give them more gold. Messrs. Bigelow & Davis have gone to the Hassayampa district to do assessment work on their claims. The l-sses of the Pine Spring mine are taking out a great deal of rich silver ore. Native silver shows itself in every piece. The Bullwhacker, a few miles to the east of Prescott, is highly spoken of. It is a gold bearing vein. Bars of silver bullion, from the Peck and Azilum mills were sent in here yesterday.

RAYMOND'S CONCENTRATOR.—Mohave *Miner*, Nov. 8: On Thursday afternoon we paid a visit to the old Lone Star concentrator, which has been lying idle so long, and which was recently purchased by Henry Raymond & Co., and is now being renovated and overhauled preparatory to starting up for the winter. The battery has been thoroughly overhauled, and the Frue concentrators put in first class condition. Amalgamating plates have also been put in, as well as many other practical and ingenious devices for saving the precious metals. Mr. Ryan, who was lately in charge of the Benson Smelting Works, is the superintendent of the mill. The mill will be started up in a day or two, and will run on tailings until every part of the intricate concentrating machinery has been adjusted to a nicety. While the mill is intended principally for working free gold ores, Mr. Ryan tells us that he will also be prepared to concentrate low grade lead ores, and promises to make any ore carrying over 10 per cent pay.

COLORADO.

MONTEZUMA MINES.—Cor. Colorado *Miner*, Nov. 6: Never, in the experience of your correspondent, has this camp exhibited as solid a front, financially speaking, as at the present time. With three or four exceptions, where large companies are working, leasing is all the "go." A majority of the lessees are doing well, and I feel safe in predicting that for want of money with which to buy it, this camp will never run short of "grub" again. The Bell mine, under lease by John Burke & Co., is keeping up its record as one of the sturdiest producers in the State. The crosscut that is being driven to cut the lode will cut it at great depth, and when that is done, look out for a mineral wonder. The Chataqua Company are employing a large force of men, and a big strike is looked for daily. The Sarsfield is being worked under lease, but your correspondent is not acquainted with the condition of that property. The Silver Worth mine is coming into prominence as one of the best paying mines in the county. A car of ore shipped from that mine last week netted 180 ounces silver and 45 per cent lead per ton. The Winning Card lode never looked better than at present, and the boys are making more money than a politician could spend.

UTE CREEK MINES.—The outlook for a bright future is very flattering. In the Great Eastern lode there is now exposed a fine vein of solid ore, which returns \$30 to the ton. The Hell Bros., who are leasing on the Humboldt lode, are preparing to make a large shipment from their workings about the last of the present month. A contract to sink the shaft upon the Andes lode 100 feet further, is in contemplation. The mines on Williams Forks have been actively worked all summer, and many of them are preparing for the winter's campaign by taking in sufficient provisions to last during the snowy season.

There is a perceptible increase in the activity among miners in Clear Creek county. Several prospects that have lain idle for years have been started up in the past few weeks. One cause for this sudden commencement of operations is the fact that the smelters are offering extra inducements to owners of low-grade mines, and run well in lead or iron. Mines on Griffith mountain that have not yielded a pound of ore for years are being brought into market as active producers, and will continue so, we have no doubt, for some time to come.

PITTSBURG NOTES.—*Elk Mountain Pilot*, Nov. 7: The tramway at the Augusta mine broke down when they were stretching the wire and it will be a week before it will be ready to make the trial trip. Scott McCullough is laying in supplies for the winter in Dark canyon for a Pennsylvania company. A. B. Mathews, superintendent of the Augusta mine, reports a rich strike of ore in that mine—richer and more extensive than any body of ore yet opened in the mine. David Smith has returned to his home in Iowa. He shipped 50 sacks of ore to the Jumbo smelter in Gunnison before he left.

CRYSTAL CITY NOTES.—Our camp is coming to the front in good shape, and those interested have gained more confidence than ever in the future of Roek Creek and it is safe to predict that this section will be one of the most important in the State. The Black Queen, is more than proving up the south slope of Sheep mountain, and with such a body of rich ore as there is to be found in this mine we can look for activity around the property. A. G. Sinsborough is fixing up for winter and will push work on his property; he has a large vein that carries copper and iron. Work has been put upon the Governor Tabor in a new opening that shows a large body of the finest kind of galena and carbonate ore. The Lost Horse is being worked and has a strong vein that is showing up well. Vic. Anderson is taking out some fine ore from the Square & Compass, and has ore that will pay to treat with a local smelter. Work is being done on the Bob Tail up North Fork, and shows considerable iron and copper.

IDAHO.

IN FROM LAVA.—Wood River *Times*: C. Clawson, W. G. Seamands and J. W. Epley got in from the Dry Fork of Antelope about 8 o'clock last evening—having made the trip in about 12 hours, by the trail. During his brief stay there Mr. Clawson made a somewhat thorough examination of the district, and he is confident that it has a very prosperous future. Only about 150 men are there now, but a large population will be supported by next spring. The ore-bearing belt is about 10 miles north and south, by 8 to 10 east and west. There are three distinct belts—the Horn Silver, at Era, which is in porphyry; the Antelope, in black lime, shale, slate and porphyry; and the Lava, which carries considerable gold in porphyry, lime and slate. Some of this ore averaged \$25 in gold in an old-fashioned Mexican arastra. These belts are all connected, and the district of about 10 miles square will be very lively when its boom shall strike it. The gentlemen named are in after supplies and will remain three or four days, Mr. Clawson returning to assay for the Snowstorm Company.

YIELD OF THE CAMAS No. 2.—Wood River *Times*, Oct. 21: Superintendent Doniphan, of the Camas No. 2 mill, came in to-day, bringing \$1400 worth of fine bullion as the result of the last seven days' run of the 10 stamps of his mill. In a few days 10 additional stamps will be started up, and the yield then brought up to \$400 per day.

HURRAH FOR THE GOLD BELT!—Ole Rorem is going to Salt Lake City to-morrow, to incorporate the Donovan mines and mill into a company. The success of the company is assured, as they have a large body of ore in sight. The Wiswell mill to crush this ore is on the way here from Boston. As soon as it arrives it will be put in place, as the mill building, blacksmith shop, boarding-house, etc., are already erected.

THE CARRIE LEONARD MINE.—Thomas J. Covert was in town to-day. Mr. Covert owns one-sixth of the Carrie Leonard mine, which has yielded about \$30,000 worth of ore this summer—of which fully two-thirds has been divided among the owners. A small force will be kept at work doing dead work in the mine until next spring, when it is expected that the force will be increased to 40 or 50 men, as there is a large quantity of stopping ore in sight already. The Carrie Leonard will therefore yield much more largely next year than this. On his return from the East Mr. Covert will open up the Tinker claim, near the King of the West, in which he owns a half interest. The Smoky mines, Mr. Covert says, will produce heavily next year, as they are pretty well developed.

THE BIG COPPER.—Hoiston *Free Press*, Nov. 7: Notwithstanding the general impression that has gone abroad that the Big Copper mines are to stop all work for the winter, we are informed that there will be a force of men kept steadily employed in taking out copper and silver ores; the recently found gold ledges will be stripped and experiments made to ascertain beyond a doubt, the true value of these finds, and a large amount of flux will be mined and baled to the smelter. About 25 wood-choppers will be given work in the timber on the claims, and several kilns will be constructed in which to transform the wood into charcoal. It is also the present intention of the company to start up the reduction works sometime this month, or so soon as there is a sufficient quantity of charcoal ahead, and run uninterruptedly on silver ores until spring.

MONTANA.

RED MOUNTAIN.—Helena *Independent*, Nov. 6: Traveling along down Beaver creek, we are right at the base of Red Mountain. Scarcely a prospect hole can be seen upon its precipitous side; but down next to the creek are several old cabins, where prospecting was done in years gone by. Following the track made by the bursting reservoir, we are soon in sight of Little Red Mountain, and shortly after strike the road leading from Rimini to the Red Mountain tunnel, which can be plainly seen. The tunnel is about 240 feet long, where a load has been cut, showing a fine quality of ore. The ore vein is well defined, very red in color and carries lead silver and copper. The location seems very favorable for the discovery of leads. The mountain is quite steep, and to the

west are many known leads, carrying valuable ores, which presumably run through the mountain. Rimini is about two miles distant. Two thousand feet from the Red Mountain tunnel, nearly due south and 1500 feet from the line marked out is the Grand Central. This tunnel is now about 40 feet in length, but as yet has not penetrated the shale and slide-rock. It is well timbered and the chances of striking leads seem quite favorable. The mountain here is very steep and many valuable mines exist on the western slope which the tunnel will strike if they extend so far into the mountain, and of this there seems to be no doubt. East of the Grand Central and southeast of the Red Mountain Tunnel is the Mineral Belt tunnel site. At the time of our visit no work had been done, but the projectors are sanguine of striking it rich and have men now at work boring into the mountain. On the south side of the mountain, opposite the other tunnels and running toward them is the South Side tunnel. It is favorably located, will strike the veins at a great depth, and if they prove rich it will be a valuable property. About four miles southeast of here is the Katie Tutnam lode, which has been stocked and a tunnel company organized. The mountain is very steep on which it is located and some very good ore has been found. It is situated close to the Frohner and Nellie Grant mines. Having looked over these prospects and taken a general survey of the rich group of mines on the west side of Red Mountain, we rode down to Rimini.

NOTES.—*Inter-Mountain*, Nov. 7: Eugene Russell & Co. have a placer claim on Three Mile creek, about eight miles northeast of Stevensville, Missoula county. It is eight to ten feet to bedrock and contains fine gold from the surface down. This season the diggings have averaged \$5 per day to the man. The Welcome creek placers, in the same vicinity, also pay. The Hudson smelter at Neihart, commenced work this week. The company has seven or eight men employed in its mine, the Mountain Chief, and have about 120 tons of high grade ore at its smelter ready for treatment. A six foot body of free milling gold ore has been struck in the Belmont, near Helena. The mine has been idle for two or three years. Burghart will work both his mines on Snow creek—the Whippoorwill and Uncle George—this winter, giving employment to from thirty to fifty men. The Big Chief, near Jefferson City, has been tapped by a 370-foot tunnel at a depth of 200 feet. The ore is 50 per cent galena, carrying about \$50 in silver and \$15 in gold. Several leads discovered at the head of Welcome gulch yield a free milling whitish gold quartz. The surface rock of a four-foot (or thereabouts) vein assayed from \$23.24, the lowest, to \$440.76, the highest, in gold. A 15-inch streak of ore in the Pleasant View mine, Sweetwater district, Missoula county, assays 350 ounces in silver to the ton. J. B. Catlin and others recently sold a placer mining bar at the confluence of Trail and Ruby creek, in the Big Hole country, to a Salt Lake company for \$5000. Silverman's new sampling works at Helena, bought their first lot of ore last Thursday, from the Bullion mine, near Elliston, paying for the galena, which assayed 58.33-100 ounces of silver, \$4.53 gold and 50 per cent lead, \$68 per ton; and the carbonates which assayed \$39.81 silver, \$4.50 gold, and 23 1/2 per cent lead, \$23.50 per ton, net cash.

NEW MEXICO.

BLOWN IN.—Socorro *Bullion*, Nov. 7: Stack No. 2 of the Billings works, which has been idle for some days, has blown in. Barries is dumping high-grade argentiferous galena from his Steel Dust mine in Water canyon. Within 60 days the Grapic smelter of this city is to be increased very materially in capacity. Colonel T. W. Hemans, in White Oaks. He meditates the erection of a stamp mill. Wm. Mahara is with us again to renew the work on his famous iron lode in the South Socorro district. This property yields 68 per cent iron ore containing \$15 in gold. The Socorro tunnel will resume work in a brief period. The exploration will be guided by means of a diamond drill. Col. J. S. Hutchason is working the Wade Hampton, March and Rattler properties in the Pueblo district. His Ambrosia, in the Magdalena district, is being worked, and the mineral is packed down the mountain side upon burros, and then shipped by rail to the Billings works of this city. McLeish & Leddy have commenced the shipment of mineral from their Bonaparte mine in Water Canyon district to the Billing smelter of this city.

COMMENCING WORK.—Jacksonville *Times*, Nov. 7: The rains of the past week have enabled some of the miners of Josephine county to commence work. Many of those in Jackson county expect to be busily engaged soon. The ground is so very dry that it will take a great deal of rain to soak it well. As the miners have been disappointed during the past few years, everybody seems anxious that they should have a benefit this winter. Whenever there is a good mining season, money is much more plentiful than otherwise. A quantity of rock from the Pilgrim ledge of Walsh & Bragdon, on Wagner creek, was submitted to the assay of Thos. Price, a well known assayer of San Francisco recently, with gratifying results to the owners of the mine. The report returned is: Gold, \$32.82; silver, \$15.30; total, \$348.21 to the ton. Alex. Watts is opening his mines in Josephine, and expects them to show up well this season. Riley Congle is in charge of them. Wimer & Sons, of Waldo, have started work at their hydraulic mines, and are making the gravel fly. This is one of the best mines in the State, and always pays well.

OREGON.

BULLION.—Bedrock *Democrat*, Nov. 7: A few days since the banking house of J. W. Virtue bought of E. M. White \$600 worth of gold bullion, the proceeds of 15 tons of ore from the Dolly Varden mine. This ore was crushed in an arastra, and there is a large quantity of similar rock now ready to be worked. As the work progresses the mine shows up splendidly.

PROSPECTING.—Mr. Watson, one of the gentlemen interested in the quartz mill to be erected on Burnt river this fall, mention of which was made in these columns some days ago, was in town this week. He is now on Burnt river making a selection of the mill site and will soon return to Portland to make the necessary preparations for the shipment of

the machinery. Ernest Nadeau, one of the owners of the Trail creek mine, has returned to the city to spend the winter. The other men will remain at the mine until the snow covers the ground, protecting the flumes from inquisitive persons who might desire to clean up what gold is left there. Messrs. Nadeau and Thibideau bought the J. B. Gardner interest in this mine last summer, and the other owners are James Odell and Walter Fernald. While he did not give us any figures, still we were led to infer that the result of the fall clean-up was highly satisfactory.

UTAH.

REVIEW.—Salt Lake *Tribune*, Nov. 9: The output of bullion, (exclusive of all ores) by operations centering in this city, as covered by current reports, has been as follows for the present year:

January	\$378,644.55
February	237,536.78
March	273,771.69
April	350,983.27
May	288,620.43
June	354,076.16
July	250,567.40
August	321,912.78
September	319,079.40
October	420,855.92

Total \$3,316,048.39
A number of bullion producers have made no reports so far, and large quantities of ore are sold of which no public account is rendered. The receipts of bullion and ore in this city for the week ending Nov. 4th, inclusive, were \$92,266.46, of which \$77,441.56 was bullion and \$14,825 was ore. For the previous week the receipts were \$138,057.72 in bullion and \$36,102.30 in ore, a total of \$174,160.02. The Ontario output for the week was fifty-two bars of bullion, of the value of \$26,112, bringing the total for the present year up to the sum of \$1,379,439.21. The double dividend for the month of October was paid on the 31st ult., and thus the stockholders have this year received \$5.50 per share or \$825,000. The Stormont sent up four bars of bullion during the week, valued at \$6980. The product of the Hanauer smelter for the week was nine cars of bullion, \$22,350; of the Germania, eight cars, \$18,517.46. Nothing new from the Horn Silver, but the claims in the neighborhood of it are looking well. Ore receipts were \$800 from the Crescent and \$1650 from the South Utah; \$6200 from the Queen of the Hills, and 35 tons, \$6175 from the Bannock, Idaho.

THE CHRISTY CO.—Southern Utah *Times*, Nov. 5: The mill has been running regularly on good ore, and we expect that the bullion output, for the month, will be better than usual. Owing to the unexpected though very favorable circumstances, the donkey hoisting engine will not be placed in position in the new shaft as soon as was expected. The ledge cut in the uprise to the station, a few weeks since, is fully three feet in width at the back of the station, and the manager found it would be necessary to stop this ore out before placing the engine in its position for working. Six inches of the ore on the hanging sampled \$594.40, and the whole vein will average over \$150 per ton. It is undoubtedly a big bonanza.

NEW LOCATIONS.—Within the past few weeks, speculative locators have been busily engaged in locating, recording and staking out prospective mines around the camp. Three locations were made last week, which take in the townsite of Silver Reef, and cover the last piece of vacant mining ground in the immediate vicinity of camp. This activity among land speculators, was brought about by the strikes in the working mines of late. The big body of ore, opened up in the Stormy King, is making north, and, at present, does not lie 800 feet from the lower end of town; but whether it will hold out, pinch or break, is simply a matter of speculation.

OTHER NOTES.—Sam Bennett shipped 12 tons of very good rock from the Thompson to the River mill this week. The 50-ton shipment, made by Josh Alphin, to the Stormont mill, from the old Bonanza mine on the White Reef, mailed \$48.70 per ton. The stopes in the Buckeye, Savage and Last Chance group of mines are looking well and are furnishing the mill with an average of 38 tons of fair grade ore per day. It is the intention of the management to start sinking the main incline from the six to the seven in a short time. Kimple & Lewis, lessees of the Leeds mine, are drifting on a six-foot vein of ore. Since they started to drift, a few weeks ago, they have broken over a hundred tons of ore. They say that the ore samples between 25 and 30 ounces per ton, and that they will begin to ship as soon as the leaching works is in operation. A train, composed of eleven teams, hauled the new tanks for the leaching works into camp last Monday. The tanks were made in San Francisco, out of California redwood. All the material is now on the ground, and the work of putting the apparatus together has been started and will be pushed forward to completion as soon as possible.

WASHINGTON.

LATEST EXCITEMENT.—Stevens county *Miner*, Nov. 6: The latest excitement among the prospectors of this vicinity is the new discovery made recently by Richard Chulson. This gentleman is an experienced miner. He has been prospecting on the Columbia above and below the Little Dalles, and on Saturday last arrived in Colville with a sack full of ore that set men on their nerves. The fact is the ore looked good enough to eat, and if they have any amount of it, it is a bonanza and no mistake. The ore contains carbonates, chlorides, bromides, galena and silver glance, and is some of the best looking rock ever brought into town. The location is about 1000 feet below Six-mile bar on the Columbia river and within a stone's throw of the river. H. M. McCartney, who has visited the strike, says a good wagon road can be built right up to the mine from the Little Dalles road for the small sum of \$50, as there is a natural pass all the way, almost free from obstacles. Interested in this find are R. Chulson, J. A. Reilly, A. E. Benoit, W. B. Moore, and one or two others whose names we have not learned. Al. Benoit and Mr. Reilly departed Wednesday morning with an assayers' outfit for the camp, where they will immediately put a small force of men to work, and open up the prospect. Deer and bear said to be exceedingly numerous in the vicinity of the mine; consequently fresh meat is plentiful.

MECHANICS' INSTITUTE INDUSTRIAL EXHIBITION

Of the City and County of San Francisco.

PREMIUMS AWARDED.

GOLD QUARTZ and PLACER MINERS' SILVER PLATED AMALGAMATING PLATES FOR SAVING GOLD.

Have been Awarded the First Premium at Mechanics' Fair for the Last Thirteen Years.

Every description of plates for Quartz Mills and Wet or Dry Placer Amalgamator Machines made to order, corrugated or plain.

OVER 3,000 ORDERS FILLED!

References from every purchaser. Full weight of Silver guaranteed on every order.

The most extensive and successful manufacturer of these plates in the United States. Will fill orders for delivery in Rocky Mountain and Pacific Coast Mining States at lower prices than any other manufacturer.

Old Mining Plates Replated. Old Plates bought gold separated for low percentage of result.

Roller Ore Feeder.

(PATENTED JUNE 24, 1873.)

This form of Ore Feeder is well adapted for its peculiar work.

Manufacturers of the Celebrated "Challenge" Ore-Feeders for any character of ores; also "Stanford Improved" Ore Feeders and Tullock's Ore Feeders for dry ores.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont St., San Francisco.

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisal Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

TUBBS & CO.

411 and 612 Front St., San Francisco

VALUABLE CHROMIC IRON MINE.

Within 2 miles of Railroad.

Thousands of Tons on Surface.

CAPITAL WANTED TO DEVELOP

Half share as equivalent, or will sell outright. Address G. W. SPAWFORTH, Lang Station, Cal.

THE FAMOUS

The most wonderful Curative Agent in the world.

Full Power Belt, for Lady or Gentleman, price \$10.

Cures without the aid of Medicine

General Debility, Nervous Prostration, Rheumatism

Neuralgia, the Liver, Disease of

Sciatica, the Kidney or

Paralysis, Bladder

Constipation

Semenal Weakness, Dyspepsia, Female Weakness,

Sick Headache, Insipient Catarrh, Insipient Consumption, Lame Back, and many other diseases.

BELT PACIFIC ELECTRIC CO.

SOLE PROPRIETORS,

330 Sutter St., San Francisco.

THE ROLLER ORE FEEDER

(Patented May 28, 1882)

This is the best and cheapest Ore Feeder now in use.

It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Punker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

Golden State and Miners' Iron Works.

Sole Manufacture, 237 First Street, SAN FRANCISCO, CAL.

INGERSOLL ROCK DRILLS

...AND...

AIR COMPRESSORS.

The Latest Improved Ingersoll Rock Drill, with Large Ports, will do 50 per cent more work than the Old Ingersoll.

MINING MACHINERY.

For Catalogues, Estimates, etc., address:

BERRY & PLACE MACHINE CO.,

PARKE & LACY, Proprietors,
12 California Street, San Francisco, Cal.

DRY WASHER for PLACERS

THE HITCHCOCK & HERSHEY
NEW DRY GOLD CONCENTRATOR.

This Machine weighs only 325 pounds; readily taken apart; packs in small compass; may be run by hand or horse power. Capacity, two tons an hour. No blowers or 6x1 fans, or quicksilver used. Frame all malleable iron. Will save a higher percentage of gold than other machines. TATUM & BOWEN, San Francisco and Portland, Agents.

Now on exhibition at Mechanics' Fair, San Francisco, where it may be seen in operation.

ANNOUNCEMENT.

The Clayton Air Compressor Works, of Brooklyn, have opened an office at No. 43 Dey Street, New York, for the sale of the Clayton Improved Air Compressors, Rock Drills, Mine Pumps, Hoisting Engines, Rock Crushers, Blasting Batteries, Wire, Fuse, and Mining Machinery in General. For Catalogue—August 1885—estimates and general information call upon or address, Clayton Air Compressor Works, Office, 43 Dey Street, New York.

[From the Engineering & Mining Journal, Aug. 8, 1885.]
The Clayton Air Compressor Works have issued a New Illustrated Catalogue and Price List. Every Mine Manager and Engineer should have a copy for reference, for none can afford to be without the information there given concerning the unsurpassed Clayton Air Compressors and other Machinery.

RICHARD C. REMMEY, Agent,
Philadelphia Chemical Stoneware Manufactory,
1100 East Cumberland St., PHILADELPHIA, PA.

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 500 South 10th St., Philadelphia. Branch Office—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

BALFOUR, GUTHRIE & CO.,
316 California St., San Francisco.

PATENT LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning
and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Guano Works, Quicksilver Mines, Lead Corroding, and all other occupations where there is dust, poisonous vapor, or bad odor.

In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.

The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

Address communications and orders to
T. E. JEWELL, Sole Agent,
330 Pine St. (Room 4) San Francisco.

Send for Descriptive Circulars containing Testimonials of well known parties who are at present using them.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et als.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,
39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

IMPROVED HYDRAULIC MACHINE.

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

HOSKIN & CO., Marysville, Cal.

JAS. LEFFEL'S TURBINE WATER WHEEL

The "Old Reliable."

With Important Improvements, making it the

MOST PERFECT TURBINE NOW IN USE

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power. Those improving water power should not fail to write us for New Prices before buying elsewhere. New Shops and New Machinery are provided for making this Wheel. Address

Of all kinds made to order. Send for Descriptive Catalogue. 17 and 19 Fremont St., San Francisco.

Alaska.

Gov. A. P. Swineford, of Alaska, has made his first annual report to the Secretary of the Interior on the condition of affairs in that district. He arrived at Sitka, September 15th, and was cordially received, save by a very few persons who, in the language of the Governor, preferred a continuance of the old order of affairs, under which, presumably, they had persuaded themselves they might individually profit much more largely at the expense of the general Government than under the new. None of the appropriations made for the support of the civil Government, or for specific purposes, appear to have reached the hands of the ex-officio Treasurer. Consequently he has no record of disbursements, all of which, with a few exceptions, the Governor says, were made by the Collector of Customs. An increased appropriation for schools is asked. The children are said to manifest more than the average aptitude in study, and are especially anxious for the establishment of English schools. A careful estimate of the population of Southeastern Alaska places the number of whites at 1900 and the natives at 7000. Some of the native Alaskans are said to be educated to some extent in elementary branches, and to have become members of the Greek, Presbyterian and Catholic churches. They are not Indians and differ in appearance, habits, language and other respects from the Indians of the United States. The Governor dwells at length upon the great natural resources of Alaska, and severely arraigns those Government agents who have represented the country as inclement to the degree that precludes cultivation or the keeping of domestic animals. Never in his travels from Lake Superior to the Gulf of Mexico has he seen more luxuriant vegetation than in Southeastern Alaska. The hardier vegetables all grow to maturity and to an enormous size, while cattle are sleek and in the best possible condition. Work on the gold mines on Douglas Island, opposite Juneau, are in full operation. The deposits are represented to be truly phenomenal, and the Governor says the mines promise to figure more largely in the mining history of the world than any yet on record. Curing and canning cod and salmon have assumed large proportions, although the business has not yet been largely remunerative by reason of the sharp competition of the Columbia river fisheries. The Indian police system is highly commended. Attention is also directed to the needs of the Territory in the matter of mail facilities. The law prohibiting the liquor traffic is said to have been disregarded. The defects in the laws governing the Territorial organization are discussed at length.

GOLD AND SILVER.—Some time ago, for the purpose of increasing the amount of gold in the United States Treasury at New York, the Clearing house agreed to furnish the Treasury with \$6,000,000 in gold, in exchange for an equal amount at par value of subsidiary silver coin, and the amount of gold to be furnished by each bank was apportioned among the Clearing-houses, in proportion to the amount of deposits carried. All the banks responded with one exception—the Broadway—which refused to make the exchange, and the Treasury therefore obtained only \$5,915,000. The subsidiary coin was left in the Treasury in this city and certificates for the same were issued to the different banks by the manager of the Clearing-house. Until recently the banks were not permitted to exchange these certificates for subsidiary coin, but about 10 days ago permission was granted to deposit certificates for such amounts as the banks might wish to draw from the Sub-Treasury. The scheme failed to create the demand that was expected, the banks to the present time having called for only about \$1,000,000. Last week the Sub-Treasury began redeeming the certificates in legal tender notes (greenbacks), and about \$2,000,000 were thus redeemed during the day. The operation was continued, and about \$2,000,000 more were redeemed. This leaves about \$1,000,000 certificates yet outstanding, which will probably be presented for redemption in a short time.

Mining Share Market.

There is no special improvement to note in the condition of any of the Comstock mines, and therefore none to record on the mining share market. Work is being steadily prosecuted to produce a paying mine in the lower levels. The middle mining section remains about as it was; work goes actively ahead. There is nothing detrimental in the indications, however, and further explorations are being conducted at very interesting points. At the north end the development work in Ophir is going ahead lively, as usual, the proposition being to extract ore from the old upper levels before long. Work in the old bonanza ground, Consolidated California and Virginia, goes straight along as usual. At the south or Gold Hill end operations are actively resumed in Crown Point and Belcher, and about 200 men have been put to work. About 70 miners, however, have been let out of the Yellow Jacket.

Now is the time to send gold spectacles home; mas gifts. C. Muller, optician, 135 Montgomery street.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some responsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

THE Fresno *Expositor* reports that discoveries of gold are being constantly made in that county, and believes that the mining interest will soon become important.

THE Nehalem coal discoveries made near Astoria, Or., are causing considerable interest in that locality.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & CO.'S
SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING NOVEMBER 3, 1885.

- 329,128.—Screw Propeller.—Joseph Belduke, S. F.
329,628.—Wash Boiler.—Martin F. D. C. Dannmeyer, S. F.
329,825.—PAVING BLOCK.—Alfred T. Elford, S. F.
329,563.—ENGINE.—Alfred E. Johnson, Austin, Nev.
329,571.—LAMP CHIMNEY CLEANER.—Mortimer D. Lamb, Butte City, M. T.
329,750.—ORE CRUSHING MACHINE.—Joel B. Low, S. F.
329,579.—EXTENSION BABY CARRIAGE.—Anthony McLean, S. F.
329,483.—APPARATUS FOR DYEING.—Ludwig Pfaff, S. F.
329,486.—PENCIL SHARPENER.—G. C. & W. C. Price, S. F.
329,602.—GRAIN SEPARATOR.—James M. Smith, Etna, Cal.
329,603.—DEFLECTOR PLATE FOR FIRE BOXES.—Andrew J. Stevens, Sacramento, Cal.
329,604.—DIVIDED CAR AXLE.—H. Thielens & H. W. Dalg, Portland, Or.
329,511.—APPLE PARSER, SLICER AND CORER.—John B. Tupper, Petaluma, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

MILL-STOCK FEEDERS.—Geo. Cottrell, S. F. No. 329,364. Dated Oct. 27, 1885. This invention relates to that class of automatic feeders which are employed to deliver mill-stock of various kinds to rolls, purifiers and similar machines. The patent covers certain points of construction and combination of devices.

APPLE PARSER, SLICER AND CORER.—John B. Tupper, Petaluma. No. 329,511. Dated Nov. 3, 1885. This invention relates to that class of apple-parsers in which the apple is carried on a rotating fork and is pared and sliced by suitable knives, which travel in contact therewith; and the invention consists in a combination of devices for making an effective and rapidly operating machine.

WEIGHING DELIVERY WAGON.—Shubael Park, Oakland. No. 328,138. Dated Oct. 13, 1885. This invention relates to a device for transporting and weighing articles in bulk. It is a combination, with a vehicle having an opening made in its floor, of a scale supported within the opening and a lever, whereby the scale may be raised above the level of the floor or depressed beneath it.

ENGINE.—Alfred E. Johnson, Austin, Nev. No. 329,563. Dated Nov. 3, 1885. This invention consists of cylinders having their axes in line, pistons fitted to said cylinders and united by a rod which connects them, rotating disks loosely fitted to said piston rods, so as to be operated by eccentrics on the main engine shaft, which extends transversely between the cylinders, and in certain details of construction. The valves are kept in contact by steam pressure, which operates them in one direction and the eccentric in another.

CRANE OR DERRICK.—Wm. S. Doan, Sacramento, assignor of one-half to Wallace Doan, S. F. No. 329,148. Dated Oct. 27, 1885. The invention relates to the class of dredging machines, and it consists in a boom-supporting mast adapted to be rotated by means of a turntable at its base, or a novel boom supported by the mast and provided with a counter-weight extension, and in certain details of construction. The object is to provide a simple derrick adapted for use on land or water, which, by reason of its construction, can be readily and easily handled.

JAMES T. CHINNICK, Elk Grove, Cal. No. 328,127. Dated Oct. 13, 1885. This windmill

head consists of a hollow perforated main head, secured to the frame of the mill, and carrying anti-friction rollers on its top and steady rollers below, a rotating tubular head fitted in the main head, and having a top flange resting on the upper rollers, and a bottom flange bearing against the lower rollers, a peculiar bracket secured to the rotating head, and adapted to carry the regulating vane, and plates or bars secured to the bracket and head for carrying the boxes of the crank-shaft.

ANIMAL TRAP.—Smith K. Reynolds, San Jose. No. 329,082. Dated Oct. 27, 1885. The trap consists of a swiveling tray or platform adapted to receive the earth which is usually thrown up by ground animals, such as gophers and squirrels; or a hammer or lock engaged by said platform or tray, and adapted to be tripped by its movement; or a suitable seat or chamber for a cartridge containing a projectile and adapted to be exploded by the hammer, and in a peculiar grapple set and tripped by the lock. The object of the invention is to destroy small animals, such as gophers, moles, ground squirrels, etc.

APPARATUS FOR WORKING DERRICK FORKS.—Cassius Stone, Walnut Creek, Contra Costa Co. No. 328,530. Dated Oct. 20, 1885. The invention relates to an apparatus for working derrick forks, by the use of which the fork having been raised, or as to discharge its load, may be again drawn back to be set for a new load. It consists of a rope attached to the rear of the fork-head, passing around a pulley which is supported from an adjustable standard at the rear of the stack. Thence over a pulley fixed near the upper part of the derrick, and thence to a winding drum, which turns upon a clutch mechanism, and a means for operating the same, so that the drum may be caused to rotate with the shaft, or allowed to remain stationary at will. The whole apparatus is easily adjustable and greatly reduces the labor of handling the forks.

GAME BOARD.—Albert F. Knorp, S. F. No. 329,395. Dated Oct. 27, 1885. This improvement in game boards consists of a novel construction by which the surface of the table may be kept true and prevented from warping out of shape. In the construction of these tables it has been customary to take a board or plank of sufficient width and length, which usually renders it necessary to make a joint at some point between the ends. Such a surface is apt to warp and get out of shape, becoming uneven by the action of the weather. In Mr. Knorp's table the board is formed of boards or strips set on edge side by side, having plates or bars extending through openings made transversely through them, and supporting sills upon which the table rests, combined with screw-bolts extending through the sills and into the transverse bars.

BARK-MILL.—Wm. A. Woods, Santa Cruz, assignor to R. C. Kerby. No. 329,113. Dated Oct. 27, 1885. This bark-cutting mill embodies a two-part hinged casing or shell having an open bottom, a peculiarly located hopper set into the casing near its top, or to one side of its vertical center, a rotating open-ended cutter-head or drum mounted in the casing, and provided with adjustable hits or knives adapted to catch and slice the bark between themselves and the lower or long wall of the hopper, and to force the cut slice into the drum; and peculiar inclined ejector-wings on the periphery of the cutter-head, adapted to force the cut or sliced bark outwardly to the open ends of the drum, from which it falls into the casing and is discharged.

BARK-MILL.—Wm. A. Woods, assignor, to R. C. Kerby, Santa Cruz, No. 329,114. Dated Oct. 27, 1885. This invention relates to a bark-mill of that class in which a rotating cutter head or drum, slices or cuts the bark against the wall of the feed hopper; suitable ejectors within the drum guiding and discharging the sliced or cut bark. This mill is an improvement on the other one issued on same date, but applied for before. The present means of carrying out the invention consists in a novel circular or annular ejector-core, conical in cross-section and formed about the hubs of the drum and within its periphery, and peculiar side wings hinged to the inner surface of the periphery of the drum and to the inner surface of the base of the core and projecting into the space between the open ends of the drum and outer casing.

NEW BOOKS ON ASSAYING.

By C. H. AARON.

PART I.—Gold and Silver Ores.—Price \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning. The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Methods; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scouring; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth; 1884. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

PARTS II AND III.

Lead, Copper, Tin, Mercury, etc.

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Manipulation, etc.; Lead Ores; Copper Ores; Volumetric Assays; Parkes' Process; Amalgamation; New Process; Preparation of Potassium Zanthate; Electrolytic Determination of Copper in Ores, etc.; Assaying of Tin Ores; Assaying of Mercury Ores; Assaying of Zinc Ores; Assaying of Zinc Ores, New Method; New Assay of Nickel and Cobalt; Assay of Chromium; Assay of Bismuth; Assay of Arsenic; Assay of Antimony; Assay of Sulphur; Assay of Salt; Appendix to Part I; Notes on Crucible Assays; Weighing by Oscillation; Appendix to Part III; The Assay of Lead; The Assay of Copper.

There are 160 12mo. pages with illustrations in the volume, which is bound strongly in cloth. Price postpaid, \$1.75. Sold by Dewey & Co., Publishers, No. 252 Market St., S. F. These are much needed books for miners and other practical men, by an intelligent miner and assayer and careful writer. They are invaluable for the mill and mine worker, and equally good for scientific experts. They are thoroughly practical books.

DELINQUENT NOTICE.

The Orleans Mining Company.—Location of principal place of business, San Francisco, California. Localities of works, Grass Valley township, Nevada county, California.

NOTICE.—There is delinquent upon the following described stock on account of Assessment (No. 12) levied on the 17th day of September, A. D. 1885, the several amounts set opposite the names of the respective shareholders, as follows:

Name.	No. Certificate.	Shares.	Amount.
Platt, Charles.....	9	59	\$295 00
Cuddehe, Thomas.....	30	10	50 00
Delano, M. H.....	31	10	50 00
Delano, M. H.....	32	10	50 00
Delano, M. H.....	33	10	50 00
Delano, M. H.....	34	10	50 00
Delano, M. H.....	35	10	50 00
Delano, M. H.....	36	10	50 00
Delano, M. H.....	37	10	50 00
Delano, M. H.....	38	10	50 00
Delano, M. H.....	39	10	50 00
Delano, M. H.....	41	12 1/2	62 50

And in accordance with law and an order of the Board of Directors, made on the 17th day of September, A. D. 1885, so many shares of each parcel of such stock as may be necessary, will be sold at public auction at the office of the Company, Nos. 934 and 936 Mission street, San Francisco, California, on Monday the twenty-third day of November, A. D. 1885, at the hour of two (2) o'clock p. m. on said day, to pay said delinquent assessment thereon, together with costs of advertising and expense of sale.

GEO. P. THURSTON, Secretary.
OFFICE—Nos. 934 and 936 Mission Street, San Francisco, Nov. 3, 1885.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

**PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS,
(\$575 00), F. O. B.**

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embury), similar to the Triumph, the Frue Vanning Machine Company owns the Embury patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

RANKIN, BRAYTON & CO.,
BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

.....MANUFACTURERS OF.....

Cast Steel Castings and Steel Forgings

UP TO 20,000 LBS. WEIGHT.

True to pattern and superior in strength, toughness and durability to Cast or Wrought Iron in any position or for any service.

GEARINGS, SHOES, DIES, CAMS, TAPPETS, PISTON-HEADS, RAILROAD and MACHINERY CASTINGS of Every Description.

HOMOGENEOUS STEEL, SOFT and DUCTILE, SUPERIOR TO IRON FOR LOCOMOTIVE AND MARINE FORGINGS.

ALSO Steel Rods, from 1 to 3 inch diameter and Flats from 1 to 8 inch. Angles, Tees, Channels and other shapes Steel Wagon, Ruggy, and Truck Tires, Plow Steel; Machinery and Special Shape Steel to size and lengths. STEEL RAILS from 12 to 45 pounds per yard. ALSO, Railroad and Merchant Iron, Rolled Beams, Angle, Channel, and T Iron, Bridge and Machine Bolts, Lag Screws, Nuts, Washers, Ship and Boat Spikes; Steamboat Shafts, Cranks, Pistons, Connecting Rods, etc. Car and Locomotive Axles and Frames, and Iron Forgings of all kinds, Iron and Steel Bridge and Roof Work a Specialty.

HIGHEST PRICE PAID FOR SCRAP IRON AND STEEL.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over other Valves and Cauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be discarded from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." "Economic" Portable Boilers.

The engravings on this page represent a style of return tubular portable boiler called the "Economic." Fig. 1 is a cross-section through the furnace which is lined with fire-brick, and Fig. 2 is a longitudinal section through the center of the boiler. The front end of this boiler is cylindrical in form and extends over the furnace, while the rear end is oval, the lower portion extending below the cylindrical part far enough to hold the short tubes leading from the furnace to the back connection. The furnace is brick-lined, and can be readily detached from the boiler when desired. The fire-brick lining is held in place by iron rods, protected from the fire, and can be easily removed and replaced when necessary. The furnaces and grate surfaces are large, and the form of the boiler and arrangement of the tubes give a very high degree of efficiency and economy. The products of combustion, going through the short leading tubes into the back connection, are carried by the return tubes through the upper section of the boiler to the smoke-stack.

Messrs. Tatnall & Bowen, of this city, agents for the coast, claim that the objection sometimes raised to a brick-lined furnace in a portable boiler, that there is a loss of heating surface, is rather apparent than real. In the furnace of the ordinary portable boiler the crown sheet is the only really effective heating surface. Owing to defective circulation the water in the side walls seldom reaches the boiling point. In the "Economic" the fire-brick lining soon becomes very hot and produces better consumption of the gases set free at a low temperature than can be had in a water-lined furnace, and the cylindrical crown sheet gives a large, effective heating surface. In the portable boiler, as usually made, the furnace is the great source of expense and danger. It is the most expensive part of the boiler to build, the part most liable to give out, and the most expensive to repair. The flat crown sheet, always subjected to the greatest heat, has the least water to protect it and is the first part exposed by low water. The sides of the furnace are ready receptacles of sediment, and are difficult to clean and liable to burn out. In the "Economic" the case is reversed. The furnace is the cheapest part of the boiler to build and repair; there are no sides to fill with mud and burn out, or flat crown sheets to be exposed by low water and cause explosions and loss of life. The crown sheet in the "Economic" is fully

protected and the boiler is as safe as a stationary. It combines with the safety of the stationary return tubular boiler, the convenience and portability of a portable. It occupies but little space, and is a rapid, economical steamer.

On account of the boilers being so short, when an engine is to be mounted on it, the dome will be left off, and a dry-pipe substituted (see dotted lines Figs. 1 and 2), and this will be done in all boilers when so ordered. These boilers are now made of steel.

Distribution of Ores.

A few weeks since we had a short article in the PRESS on this subject, in which attention

the Pacific Division are independent of volcanic action, but the association of eruptive rocks with ores is a rule, with comparatively few apparent exceptions, and in many cases the agency of solfataric action is manifest. This has long been recognized by observers.

That there are relations between the rocks inclosing ore deposits and the character of the ores has been known to miners for centuries, but the study of the nature of this dependence is comparatively new. The census collections and data appear to confirm such relations. Lead ores are almost invariably accompanied by limestone, and veins in granite present only a very small number of associations of minerals, which are possibly reducible to a rough ore.

Mineral and Agricultural Land.

One of the few weak points in our code of mining laws is that relating to mineral lands, as opposed to those of an agricultural character. Owing to the system of taking proofs as to character of the land, a great deal of mineral land has gone into the hands of agriculturists. We recently gave an article concerning a case in Santa Clara county in this State, where farmers, with no knowledge at all of mines or minerals, had testified that certain tracts were more valuable for agriculture than mineral, where there were several mines on the tract, one of which was worth about half a million of dollars, fully developed, with machinery, furnaces, etc. Most

of these farmers were Portuguese or Italians. They knew nothing of mines or minerals whatever, so could swear that they thought it more valuable for farming than mining, with clear consciences.

Men with no knowledge of minerals, ore or mines but accustomed to agricultural pursuits only, can easily testify to the fact that land is better for agriculture than mining, because they would know nothing at all of its value in minerals. Unless some one has a mine on the tract or is going to mine there, there is no one interested enough to con-

tradict the evidence of the agriculturist, and the land passes out of the mineral land sections of the country. In this way a great deal of good mineral land has been taken up as agricultural.

In this connection a recent decision of the Supreme Court of the United States is of interest. The decision was rendered in two public land cases brought upon an appeal from the judgment of the Supreme Court of Dakota. The first was an action to recover a parcel of mineral land upon which is built the city of Deadwood. The land was entered and paid for in January, 1878, and in the June following the Probate Judge, acting as the trustee for the town, entered the same land. The Supreme Court holds that no title from the United States to land known at the time to be mineral land can be acquired under the pre-emption, homestead or townsites laws. The mining claim of the plaintiff in the case and the title thereto had actually passed to him before the Probate Judge took the initial proceedings. The United States had therefore nothing to convey. The judgment against the town is affirmed. The other case is similar, except that the town of Central City, Dakota, made no entry. The judgment against the town was affirmed.

"ECONOMIC" PORTABLE BOILERS.

was called by Government geologists to the fact that in the region west of the Rocky mountains there are four ore belts. These four distinct belts appear to have an intimate connection with the four great orographical changes which the region has undergone during its geological history. In the "Geological Sketch of the Pacific Division," by Geo. F. Becker, the features of these four belts are described. This theory of the relation between the ore belts and lines of uplift is, of course, not to be understood as equivalent to the assertion that the deposits are to be found only along a single line representing the actual main fissure of the uplift. One is apt to think of the dislocation attending an orographical change is confined to a single vertical or highly inclined surface, but every geologist is aware that this is not an exact view. Single fissures in the earth's crust are very rare, and parallel sets of fissures with cross fissures and stringers into the surrounding country are the rule, even in the case of insignificant cracks. In disturbances such as those of great uplifts a considerable belt of country is necessarily crushed and torn. The breadth of such a zone must be measured usually in inches.

It may be that some of the ore deposits of

Deposits in metamorphic rocks, too, though more varied than the others appear to represent but a few types.

In the "Geological Sketches of the Precious Metal Deposits of the Western United States," by S. F. Emmons and G. F. Becker (for the census), the determination of the ore and gangue minerals in the country rocks, and the kind of deposit, are introduced, county by county, and the tables given contain much information of value to miners and geologists.

PLUMAS NOTES.—Our traveling correspondent, who was last week at Quincy, Plumas county, writes us that mining matters thereabouts are quiet, chiefly for the want of water. There is a bright future, however, especially when the Mohawk railway, projected to the junction, is completed. Two miles of the road from the junction end is now graded. The recent rains brought rejoicings among the people, giving the miners a chance to reap a small harvest before the depth of winter. The town and surroundings of Crescent Hills seem to have caught the dull times, but our correspondent heard of claims being jumped, indicating that there must be something there worth having. At Eureka Mills there are many Cornishmen.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

An Experiment.

[Written for MINING AND SCIENTIFIC PRESS by C. H. AARON.]

It has occurred to me, as it has to others, that a convenient method of assaying zinc might be got out of the well-known interferences of that metal in the assay of copper by the method of decoloring an ammoniacal solution by a solution of potassium cyanide.

My plan was, to add to the assay solution of the zinc ore, previously freed from copper, if necessary, a fixed quantity of a titrated solution of copper; then proceed as in a copper assay. From the excess of copper indicated, above that known to be present, the quantity of zinc in the assay might be calculated very simply if varying proportions of zinc would produce a uniform proportional difference. The former I find to be the case, but only under conditions which seem to be practically unattainable in an assay.

I worked with solutions of copper sulphate, zinc sulphate, and potassium cyanide: the actual quantity of zinc and copper present being immaterial for my immediate purpose, which was to find out if, by taking a constant quantity of the copper solution, and adding thereto varying quantities of zinc solution, the quantities of cyanide solution required to decolor, would vary in any ascertainable ratio. It is not necessary to occupy your space by a detailed account of my experiments. I made several dozens of tests, at first with weak solutions and uniform volumes of ammonia, which gave results so nearly proportional that I was in great hope of success.

Continuing my experiments, with stronger solutions, startling discrepancies were found. In one series, it appeared as though a large proportion of zinc interfered less, relatively, than a small one. I was not discouraged by this, seeing an easy way out of the difficulty, provided the variations were regular; but in some special tests the reverse effects were observed. As is often the case in such empirical work, a number of coincidences occurred tending to mislead.

Such experiments generally result in something useful even if not in the attainment of the desired end. I have given up the idea of getting even an approximately reliable assay of zinc in this manner, but I have satisfied myself on three points.

1st. The presence of zinc does materially affect the result of a copper assay by this method, though some assayers entertain an opposite opinion, and it may make an enormous difference, especially when the ore is poor in copper and relatively rich in zinc.

2d. The variation produced by a given proportion of zinc to copper depends largely on the proportion of free ammonia present, a condition which can hardly be controlled in an assay, though it may be in a set experiment.

3d. In the absence of zinc, the presence of a great excess of free ammonia causes a higher result in the copper assay, but, within reasonable limits, the difference is not large.

In the presence of zinc, the effect of an increased proportion of ammonia is surprising. With one volume of my zinc solution to one of the copper solution, and a certain quantity of ammonia, a quantity of potassium cyanide solution represented by 27 was required in addition to that which was necessary to decolor that quantity of copper solution alone. With a larger quantity of ammonia, the coefficient of the cyanide solution was increased to 35, and with still more to 63. This may account for the diversity of opinion among assayers as to the extent to which zinc interferes in the assay of copper.

In one instance of an ore assay, some time ago, I got, apparently, 8½ per cent of copper by the cyanide assay, where other methods, including the Swedish, showed that only 2.3 per cent were present.

I also satisfied myself that the salts of ammonia have an influence on results, so that there seems to be no hope for this apparently promising rapid method for zinc.

The practical deduction from my experiments, aside from the consideration that it may save others the trouble of going over the same ground, is that, in assaying copper by the cyanide process, the proportion of free acid in the solution should be as small as possible, in order to avoid forming an undue quantity of ammonium salts on the addition or excess of ammonia; no more ammonia should be used than is necessary for the solution of all the copper, especially in the presence of zinc; and, if the zinc is in considerable proportion to the copper, the method is worthless as a copper assay, unless the copper be first separated by precipitation or otherwise from the zinc. The remarks as to acid and ammonia apply also to the making of the solution of a weighed quantity of pure copper for the purpose of standardizing the cyanide solution, and of check assays.

In the assay of copper, I think the cyanide process should only be used where rapidity of execution is important, approximating results will suffice, and zinc, beyond mere traces, is absent.

Montana Mines.

Missoula.

[Written for Press by our Traveling Correspondent, R. G. HUSTON.]

Missoula is situated on the right bank of the Hellgate river, a short distance below the mouth of the canyon, and contains about 1200 inhabitants. It is a general distributing point for the farming communities of the Bitter Root, Hellgate and Missoula valleys, and the repair shops and round-houses for this division of the railroad are here. At this point they are compelled to double up their motive power to go over the divide from Missoula to the Jocko. On his piece of road, some 15 miles from Missoula, they have the highest trestle that is in use by any railroad in the Union, being 226 feet high. It seems a dizzy height to run large and heavily loaded trains, but there seems to be no fear of its solidity.

The general merchandise interests are well supplied by Messrs. Eddy, Hammond & Co. and Messrs. Worden & Co. The town also supports two weekly newspapers—the *Times* and the *Missoulian*, each of which are up to the average county seat paper, it being the county seat of Missoula.

I was most surprised on being shown the fruit grown in town. Mr. G. B. Hartman has an orchard down on the bank of the river that is fully equal to our California orchards in variety and amount of production, and as for quality of apples, I think it surpasses anything that we have down in the valleys. He has all kinds of plums and cherries and pears, raspberries, strawberries and blackberries, and in fact, everything that we grow here can, except, perhaps, peaches. He had strawberries this year, 14 of which filled a quart measure. That sounds like a fish story, but was vouched for by so many that I made a note of it, anyway. Wheat producers have from 40 to 50 bushels to the acre; oats, from 70 to 80; barley, the same, and it is not an uncommon occurrence to see potatoes weighing three pounds. Cabbages run as high as 40 pounds to the head and turnips from 10 to 25 pounds those I saw myself.

Like all parts of this country, Missoula has her mining interests, which they think at some time or other will fill her coffers with gold and silver in plenitude. The Welcome placer mines on the east side of the Bitter Root valley, are yielding wages to a few men, and have some quartz that is said to be good. One lead called the Mary Anne, has a tunnel run for some distance; also has a shaft down 40 feet, and at that depth shows a ledge 20 feet wide of decomposed quartz, and from assays made it runs from \$25 per ton upwards. It is located where it is easy of access, and will probably develop into a good property. It is owned by Mr. H. H. Dickinson and Dr. Chouquette and others, of Missoula. There are also some ledges located near the town, but as they are undeveloped, nothing much can be said of them. On Lo Lo fork of the Bitter Root, there have been some fine copper prospects found, showing from 35 to 60 per cent copper. They also carry some gold, but are comparatively undeveloped.

Bear Gulch.

The glory of Bear Gulch's placer mining days has departed, but there are yet quite a number of the old miners working over the old ground, and picking out spots that have been overlooked in the more prosperous days of the place. I spent one night there in company with an old mining acquaintance, R. B. Loomis, who in company with a gentleman named Stone is developing a location called the Haparanda, and has a ledge of fair looking rock which prospects some in free gold. They are running two tunnels on it and will certainly ascertain soon if it is valuable or not, as they have the nerve and energy to prosecute the work. Joaquin A. Biscal still presides over the postoffice and store—the only one general supply store in the camp; consequently he has a monopoly in that line, but he does not receive the condemnation of his patrons, as the railroad company does; and the right man in the right place is the man to use.

Drum Lummon Mine, Marysville.

Is in Lewis and Clarke county, 20 miles northwest from Helena, on the headwaters of Silver creek. It is reached by stage from Helena twice a day. The mine was discovered by Thos. Cruse in 1878, and was worked by him in a small way until 1883, when it was sold to an English company operating under the name of the Montana Company (limited), with a capital stock of \$3,000,000. With the ample means at their disposal they have placed on the property one of the finest plants that there is in the West. The ore being low-grade it was necessary to prepare to work it properly in order to make returns to the stockholders, and they have supplied themselves with all the modern appliances for collecting and saving all the precious metal their ore contains. The mill contains 60 stamps and they crush about 100 dry tons per diem. They have been experimenting with four Frue Vanners and are now preparing to put in 24 more of them.

That is evidence that the result with these concentrators was satisfactory to the company. They have their mill and works lighted with an electric plant using the Brush system. The mining is all done by the compressed air drill, the National being the pattern used. I must confess that it is an easier manner of polishing

the head of the drill than the old sledge-hammer process. They are using eleven of these air drills, and they have no difficulty in keeping the mill supplied with rock. They are now working a force of 135 men, 65 in the mine and 70 in and around the mill, and I think there is nearly as many more who gain their livelihood from this same source, but indirectly.

The prosperity of the mine dates from the time Mr. R. T. Byliss assumed the management, who is ably seconded by Henry Bratnoher as mine superintendent, who, by the way, was one of my old time friends of 20 years ago, and to whom I am indebted for many courtesies shown me during my stay in the town. He has made quartz mining a study for many years, and is now reaping the benefit of his application, and the compliment is mutual, for, without a doubt, the company could not find a man who would cater to their interest in the manner he does. The mine paid a short time ago a fifteen per cent dividend, and from the present outlook have enough of their mine drained to last their present milling capacity for nearly 10 years. The lower level of their mine is in much higher grade ore than near the surface. They just struck some rock in the north end of the lower level that will run up into several hundred dollars to the ton. That is base ore, and they will have to ship to a smelter to work. The gross income of the mine can be safely estimated at \$1,000,000, with an expense account of less than 40 per cent, so you can readily see that it will be a handsome paying property for years to come. Just at present R. M. Breierson is acting general manager, but Mr. Byliss is returning from England and will undoubtedly resume his old position.

Marysville is quite a thriving village. The wants of the public are duly taken care of by Mr. Lighthody, of the American house. The Drum Lummon hotel, kept by Annie Dillon, is also a homelike place, and the Marysville house, by Mrs. Schaffer and her daughter, is a popular hostelry for ye honest miner. General merchandise, J. D. Courade & Bros., Jurgens & Price and Smith & Co., and other branches of trade are well represented, as is the usual case in mining camps like this close to a large town.

The Boston and Montana Mining Co.

Are working the Gloster mine, some three miles from Marysville. The mill and mine lie about half a mile apart, and the ore is transported to the mill by a cable tramway: the loaded car going down bringing up the empty one, also carrying lazy newspaper men up and down who wish to secure subscribers to their periodicals.

They have just completed their engine house at the hoisting works, which is certainly a finely appointed works as are needed in any country. The engine is 500 horse-power, furnished with the O'Neill cut-off. It is furnished with the Behr indicator, these only being used in two other mines in the West, the Horn Silver in Utah, and the Basset mine in Colorado. They use a compound leverage brake operated by pedal pressure, and when the brake is set it is impossible for the ponderous engine to turn a wheel. The hoisting apparatus is thrown in and out of gear by hydraulic pressure, and, in fact, everything about the mine is first class. F. L. West is superintendent of the mine, and seems to be peculiarly fitted for his position, and, having had large experience heretofore, is fully capable of running it in shipshape. The mill of 60 stamps is equally well-appointed, and is capable of handling about 150 tons per day. The ore, like the Drum Lummon, is gold-bearing. The ledge matter is not so solid as the Drum Lummon, and consequently they have to work it by hand drill. It consequently takes more than the other mine to get out the same quantity of quartz. They are working some 200 men in and around the mine and mill, and must necessarily give employment to many more, as the item of wood alone must give employment to a larger number. Messrs. Muth & Co. attend the wants in general merchandise here, and the other Marysville dealers all run wagons in, and then there are the usual amount of saloons and boarding-houses that are found around a camp of this kind.

We learn from the *Independent* that the company up to January 1, 1885, disbursed to its stockholders \$300,000. The probable result since that time I could not arrive at, as the general manager, Mr. Childs, was not disposed to be communicative, and outside reports say that the output is from \$80,000 to \$90,000 per month.

The old Whippoorwill mine and mill is some little south of the Gloster mine. The mine is worked out, or supposed to be, but the mill is soon to be started up by Messrs. Cutter & Hickey, on rock from the Enterprise location, some of which prospects very rich. They are sanguine of making it pay. They have a tunnel in 300 feet and have five shafts down some 50 or 60 feet. In some of those shafts they have good ore and think that there is small pay in their tunnel.

Messrs. Cutter & Hickey are also running the Mount Pleasant mine and mill. It is free-milling gold ore; are running six men on mine and four in mill. The ledge runs from two feet in width to 10 feet; mill yield about \$35 per ton. They seem to be well satisfied and are running right along. Cold weather freezes up their water supply so they will soon have to suspend for the winter.

Two miles further up over the divide is the noted Penobscot mine, which Vestal made

\$500,000 out of so easily, and then lost again. The mine was run in a very extravagant manner, "gilt edge," you might call it, and when they got off the big pay they had to shut down. It remained shut down for five or six years, and then the whole plant, mine and all, sold to Mr. Longmaid for \$4000. He commenced in a modest way as his means would admit of, and his first clean up was \$8000, with but little expense, and now he is working 12 men in the mines, and seven around the mill, and things look fairly prosperous around the old works.

The Albion, or Bald Butte company is located on mills from the Penobscot, south. It is owned by Messrs. Tatem, Chumasero & Co.; is free milling gold ore with a small percentage of silver, but they are not prepared to work it for what silver it contains. It mills an average of \$18 per ton gold, and they are able to make it pay that way. The incline is down 180 feet. The lower levels are run 120 feet each way, and at the 100-foot level is run 150 feet each way. Veins run east and west, pitching to the north: size of vein averages five feet all through. They have a 10 stamp mill on the property, and are doing well. The mine is managed by Pat Powers, an old pioneer in quartz in this territory, having managed a mine on the old Whit-lack Union lead at Unionville.

Hints for Lubricating.

[Written for the Press.]

The days of lard, sperm, castor and whale oil as lubricants are fast passing away. With the discovery of the new processes for refining petroleum oils, the fact dawned that the prices at which "straight, pure animal and fish" oils are furnished cannot be paid. A moment's reflection will suggest that precisely where the world would be to-day without the privilege of burning kerosene, there it would be without the privilege of using petroleum lubricants. Petroleum gives to-day the only good and satisfactory light and lubricant. Where now are all the old tallow, mutton suet, "drippings of sweet oil," olive oil, etc., used by our fathers in our boyhood days? Why, the enormous increase of machinery since then would render us now without any oil with which to lubricate, if it had not been for the discovery of petroleum. There would have been an oil and fat famine. The great improvements made continually in the distillation of petroleum oils, and the progressive discoveries in regard to their possible combinations with vegetable and animal oils, give to the science of lubrication at present essentially a character of change.

This is why it is so customary to hear purchasers of lubricating oils state that they know nothing about lubricating oils and complain that the oil salesmen often deceive them. If the purchaser would make the experiment he would often discover that he knows quite as much as the salesman, and the salesman in turn quite as much as his principal. How much accurate testing and scientific preparation of oil, think you, there is in California and on the coast? Of the oils marketed here from abroad, how many are of constituents known to those who sell them?

The true remedy is for the purchaser to employ some simple tests like those referred to in this journal recently. The moment it is understood by him that an oil which is inflammable at a degree under 350° Fah. is unsafe to use around his works, he will spend \$4.50 for a pyrometer, which will quickly show him how safe an oil which tempts him by its cheapness really is. When he knows that an oil, no matter what its fire test, should have a specific gravity of 28° to be a good lubricator, he will invest, perhaps, \$1.50 for an oleometer, which in a moment makes any oil disclose its secret. Not every oil shown to a purchaser is worthy of being tried. But the moment that the purveyor of oil knows that his goods are not to be taken on his word, but scientifically proved, the quality of the oils offered will at once be improved.

CHARLES J. WOODBURY.

123 California St., S. F.

Why Inyo County is not Prosperous.

EDITORS PRESS:—I think the following will give the reasons why Inyo county is not the most prosperous mining county in the State of California:

The capitalists who invested thousands of dollars to develop claims, for which they paid large amounts of money, as a general rule send men to manage and develop their mines who had neither a theoretical nor practical knowledge of mining. But if a common miner were to apply for a position as clerk at one of their offices they would laugh at him, even if he could prove his ability. Bad management caused whole districts to be abandoned, but a lot of fossils, who call themselves prospectors, remained behind, and as soon as the law permitted and sometimes before, located whole districts, and relocated them from year to year. They act like the dog in the manger; they will neither work their mines themselves nor let any one else work them.

In every mining district in Inyo county there are mines which contain plenty of good ore. The law allows the fraction of a year to do \$100 worth of work, and if the locator fails to do the amount of work required he should be debarred by law from relocating that claim.

MINER.

Experiments in Roasting and Amalgamation.

Mr. C. A. Stetefeldt, the well known mining engineer, formerly of this city, has published a report on the metallurgical treatment of gold ores of Las Minas, Zemelehuacan, State of Vera Cruz, Mexico. The experiments on roasting and amalgamation made there are very important, and we make the following extracts from the report. An average of 10 assays from this San Anselmo mine, gave 0.567 ounces gold per ton; average samples from Muertos mine 0.450 ounces per ton; average sample from Marie Antoinette mine, 0.325 ounces per ton gold. The grade of ore from the mines can be kept up to \$10 or \$11 per ton or even more.

The Metallurgical Treatment of the Ore.

That the gold ores of Las Minas are not fit for raw amalgamation, can be seen "a priori," and the practical tests made at the mill have been an entire failure. Such ores can only be prepared for subsequent beneficiation by a complete roasting. Hence I directed my first efforts to roast the ore dead. By that I do not mean only a desulphurization of the pyrites, and a decomposition of the sulphates formed in roasting, but also a higher oxidation of the magnetite to ferric oxide.

Roasting Experiments.

The ore was crushed wet by stamps, with No. 40 screen on the mortar, and allowed to settle in a tank. In the sluice-boxes, between the battery and this settling-tank, the coarser particles of the native gold were caught. This arrangement was made in order to avoid errors of sampling, produced by coarse gold, in subsequent metallurgical experiments. It will be noticed that some of the ore charges I have worked are considerably lower in value than the average of the ores. The statement above explains this fact.

The roasting was done in a small reverberatory furnace, with a rather ill-shaped hearth, having dead corners between the working-doors that could not be well reached with tools. A charge of 500 pounds was all the furnace could conveniently take, but generally not more than 200 pounds were roasted, this quantity being more than sufficient for my metallurgical experiments. The moist ore was made completely dry, screened, and all lumps broken up, before it was charged into the furnace.

Charge No. 1.—San Anselmo ore, with 64 per cent magnetite. The charge contained, after 4½ hours' roasting, 44.8 per cent magnetite. The solution, from a sample leached with water, gave no copper reaction, the copper sulphate being already decomposed. Some aluminium sulphate was found. After 14½ hours, the magnetite was only reduced to 42.3 per cent. After 16½ hours, one-half of the ore was discharged. It still contained 39.6 per cent magnetite.

Charge No. 2.—To the ore remaining in the furnace, 2½ per cent of salt was added, and the charge stirred for 1 hour. It was now drawn into a pile and left in the furnace, firing being discontinued. After 4 hours the ore contained 20.7 per cent magnetite, and after 8 hours, 19.2 per cent. The ore was discharged after 22 hours. The magnetite had increased to 24.5 per cent. A sample, tested for copper, showed that in one ton of ore 0.44 pounds of copper were present as cupric chloride, and 1.32 pounds as cuprous chloride.

Charge No. 3.—Muertos ore, with 47 per cent magnetite. This charge contained, after 5 hours' roasting, 35.7 per cent magnetite, and considerable copper sulphate. After 7 hours, 30.5 per cent magnetite was found, and the copper sulphate had been entirely decomposed. After 17 hours, one-half of the ore was discharged. It now contained 20.0 per cent magnetite, no copper sulphate, but some aluminium sulphate.

Charge No. 4.—To the ore left in the furnace 3½ per cent salt was added, and treated like Charge No. 2, with this difference, that the furnace was kept hot by continued firing. After 3 hours the ore contained 6.2 per cent magnetite, and much copper chloride. After 5 hours the magnetite had increased to 10.7 per cent, remaining at the same figure after 8 hours. The fire in the furnace was now stopped, and the ore discharged after 15 hours. It contained 11.3 per cent magnetite. The cupric chloride had entirely disappeared, and only 0.6 pounds of copper were present as cuprous chloride in one ton of ore.

Charge No. 5.—San Anselmo ore, with 65.7 per cent magnetite. Mixed at once with 5 per cent salt. After 4 hours' roasting, a sample contained 1.6 per cent magnetite, and considerable cuprous chloride. After 7 hours the magnetite had increased to 2.6 per cent. Firing was now stopped, the charge drawn into a pile, and left for 13 hours in the furnace. After discharging, the magnetite had increased to 5.6 per cent. Very little cuprous chloride was present, hardly sufficient for determination. A soluble aluminium salt was still left in the ore.

Charge No. 6.—San Anselmo ore, with 67.2 per cent magnetite. Mixed at once with 5 per cent salt. After 1½ hours, the magnetite had decreased to 18.4 per cent; after 4½ hours, to 1 per cent. After 5½ hours the ore was discharged. It now contained 2.5 per cent magnetite. In one ton of ore there were present 0.2 pounds of copper as cupric chloride, and 0.6 pounds of copper as cuprous chloride.

(Continued Next Week.)

California Labor Statistics.

Returns have been received by the Labor Commissioner from Sonoma and Sierra counties. In Sonoma there are 2000 farm hands employed at the average wages of \$25 a month. There are 1525 Chinese, including 20 females, none of whom are married. They are paid \$20 a month. The amount annually paid to the Chinese in this county is \$450,000, 90 per cent of which is sent out of the country. Of these Chinese the Assessor says: "Their presence keeps thousands of white women out of the laundry business, hog and grape picking and numerous other industries." Their sanitary habits are "bad, filthy, the worst in the world."

The Assessor says that no mechanic desiring work need be idle. There are employed mechanics with average wages as follows: Bakers 30, at \$2.50 with board; brewers 10, at \$2.50 and board; blacksmiths 75, \$2.50; bookbinders 2, \$4; brickmakers 50, \$2; cannery employees 100, males \$1.50, females 75 cents; carpenters, 100, \$3; wagon-makers 10, \$3; cigar-makers 20, \$2.50; confectioners 15, \$2; coopers 50, \$3; distillery employees 100, \$2.50; dairy employees 200, \$1 and board, gunsmiths 5, \$3; marble-cutters 30, \$3; millers 50, \$2.50; saddlers 100, \$2.50; shingle-makers 100, \$2.50; shoemakers, 100, \$2.50; soda works employees 20, \$2.50; stone-cutters 400, \$2.50; tailors 100, \$3; tanners 20, \$3; tinsmiths 40, \$2.50; upholsterers 10, \$2.50; wine manufacturers 100, \$3; willow-ware workers 150, males \$3.50, females 75 cents; quicksilver miners 50, \$3; railroad employees 200, \$2.50; street road employees 2, \$2; stage drivers 20, \$2.50; teamsters 50, \$2.50; draymen 30, \$2.50; railroad and express agents, 50, \$3.50; auctioneers 3, \$5; harpers 100, \$2; bookkeepers 150, \$3; bricklayers 75, \$3; bank clerks 20, \$7.50; express company employees 5, \$3.50.

Insurance clerks 25, \$3; merchandise clerks 200, \$2.50; government clerks 8, \$7.50; cooks 100, \$1 and board; dentists 15, \$4; civil engineers 5, \$3; stationary engineers, 15, \$3; artists 10, \$2; glaziers 15, \$2; journalists 10, \$3; hostlers 100, \$1.50 and board; lumbermen 30, \$2.50; milliners 30, \$1.50; painters 60, \$2.50; plasterers 20, \$2.50; printers 100, \$3; photographers 15, \$3; schoolteachers 150, males, \$3, females \$2.25; servants \$2.00, \$1.50; telegraph operators 50, \$3; telegraph messengers 20, \$1.50; waiters 150, \$1.50; watchmakers 20, \$3; well-borers 2, \$3; woodcutters 150, \$2.50; artisans not mentioned above 300, \$2.50.

In Sierra county there are 510 Chinese, 50 of whom are females. Most of these are miners, about 50 being cooks at \$30 per month. Mechanics are employed with wages as follows: Brewers 5, \$2.50; blacksmiths 30, \$3.50; brickmakers 5, \$3; carpenters 20, \$5; dairy employees 50, \$1.50 and board; ironmolders 3, \$3 and board; machinists 2, \$5 and board; pattern maker 1, \$6 and board; shingle makers 5, \$3 and board; tinsmith 1, \$4. There are 1000 miners who get \$2 per day and board; 25 school-teachers at \$80 per month and 30 servants at \$16.

PATTERSON MINES.—The two latest and most important mining strikes or excitements in this section of country, and which are attracting the most attention, are those of the Patterson Consolidated and the New Patterson mines in the Patterson district, in this Mono county, and the Lapanta mine, near Hawthorne, in our sister State of Nevada. While all are rich and promising strikes, and the capital at once invested in the Lapanta, the Patterson district mines present a far better outlook for capital to take hold of them. The Hawthorne mines, although said to be rich, are in limestone, with no defined and permanent ledges, and no guarantee that they will continue to pay for any length of time; but our Patterson district mines are in a defined ledge, which has been traced for miles, and many locations made thereon, and the ore from the Patterson Consolidated is being worked at the Eclipse mill, belonging to the company, with gratifying results, and as the work progresses in the Patterson Consolidated and New Patterson, the greater is the guarantee of their permanency. Several experts who have examined the new mines in both districts, unhesitatingly pronounce the Patterson mines the most promising. The mines in the Patterson district offer superior inducements to capital to invest in them. In this district there is an abundance of wood and an unfailing supply of water for reduction works. Lumber and all other supplies can be delivered in the district at reasonable figures, which will enable mine owners to work their mines cheaply and realize a profit from the lowest grade ores. The ores of the Patterson mines now being worked average probably from \$75 to \$100 a ton, but the large bodies of ore in sight, coupled with the facilities for reducing them, will make them valuable mines worth \$25 ore. Capital will travel further and invest in mining property that cannot make near so good a showing as our Patterson mines, but "distance lends enchantment to the view," and as our mines are within thirty-six hours' run from San Francisco, they will not attract the attention they would, were they in Idaho, Montana or Alaska.

—Bridgeport Chronicle.

THE ARIZONA Territorial Insane Asylum is to be erected about two miles outside of the town limits of Phoenix.

Hawthorne District.

Too discovery of the Lapanta mine at Hawthorne, says the *Inyo Independent*, has given a great stimulus to prospecting for mines; the whole country around Hawthorne swarms with prospectors, and many discoveries have been made recently that give fair promise of turning out well. Just west from the Lapanta mine the hills are found to contain very many ledges of silver bearing ore. Some of these assays high. Samples sent from a claim about two miles west from the Lapanta were assayed at the office of the Manhattan mine at Austin; these samples assayed \$26.14 a ton. The claim belongs to the Mining Recorder of the district, George Box, and is called the Red Bank. In the same locality are at least half a dozen other claims, all of which contain good ore; but on none of these has work enough been done to show the extent of the ore bodies.

About six miles farther south some fine ore has been found within the last 10 days, and the general appearance of the country is indicative of the presence of good ore bodies. Mining speculators in San Francisco and big mining companies at Austin and Eureka, Nevada, have experts in the district, looking out for chances to get hold of promising mining claims. A hindrance to prospecting is scarcity of water, little or none being found in the district. With the first rain or snow that falls the number of prospectors will be greatly increased. All the while men being busy with other work, Plutes are hauling water from Hawthorne to the mines, and with their miserable crow-bait skeletons of horses make big money selling the water at \$3.50 a barrel.

The town of Hawthorne is now the center of greater mining activity than exists anywhere else on the Pacific Coast. On all sides the work of prospecting is pushed vigorously, and discoveries that promise well are frequent. In the town there is at least four times the volume of business done now that was done three months ago. Merchants, hutchers, hotels, saloons and restaurants all are doing a good business. If the people of Hawthorne are wide awake, there is a bright future before them. Beyond all doubt they are surrounded by a rich mining region, all the ores from which must be brought to one common center to be worked. The water supply will determine where this center shall be. In the mountains west from the town plenty of water can be found within reasonable distance, if a sufficient supply is provided and supplied at reasonable rates. Mills and reduction works will be built, and Hawthorne will have such prosperity as was never dreamed of when the town was founded.

IDAHO.—Edward Stevenson, Governor of Idaho, has made his annual report to the Secretary of the Interior upon the condition of affairs in that Territory during the past year. He says that the crops of this year will be placed at half crop as compared with that of 1884. Notwithstanding the rapidly increasing population, products of the soil are amply sufficient to meet the wants of the people and leave a small surplus for export. The Governor points to this necessity for extending the United States survey lines in the northwest portion of the Territory so that settlers may locate thereon. The mining in ores is said to be in a very prosperous condition now, and rich mineral districts are being discovered and explored, prospected and worked with great success. The Wood River mineral belt is yielding ore assaying from 100 ounces to 350 ounces. The great Salmon river basin continues its outpouring of gold and silver, as in former years. The new lava district is fast coming to the front. The shortness of the working season has retarded the development of rich and extensive mines in the Sawtooth district, but when systematically opened and worked these mines are expected to take a place among the best paying camps on the Pacific Coast. The Governor says that not half the truth has been told of the richness and extent of this placer mines on Snake river. The Coeur d'Alene section receives most favorable mention. The Lost River copper mines, according to expert testimony, are remarkably rich. The financial condition of the Territory is said to be satisfactory. The cash on hand exceeds by \$5500 the Territorial debt. The total assessed valuation of property for 1884 was \$15,497,578, an increase of \$1,509,000 over the preceding year. A strong plea is made for the liberal construction of the Desert Land Act. The population of the Territory is set down at \$75,000, and the value of the gold and silver product during the past year is estimated at \$5,486,000.

THE Sacramento Bee says: Felipe Parkeman and Franco Parkeman, of Guanajuato, Mexico, arrived here Tuesday, accompanied by Louis Palmer, of San Francisco, who acts as interpreter. They have been making a tour of the mines in Montana and Idaho, and have visited Grass Valley and Nevada City in order to inspect the machinery. They are very wealthy and own about twenty mines in Mexico, which are worked in a primitive manner, 300 mules at one mine doing the work that a steam engine might do, and 100 men attending to the mules. The Mexican miners were very much astonished by the wonderful machinery they saw upon this trip and will order much like it for use in their mines in the tropics.

SNAKE RIVER GOLD.—Some more of the Plowman prospecting party returned a few days ago. Wm. Hooten, one of the number, exhibited a sample of this cement that contains the gold which led them to take the trip. It was about as large as your double fist, almost as heavy as galena, and full of many-colored and beautiful pebbles ranging in size from a homeopathic pill to an English walnut. The cement is bluish in color, fine grained, and so hard as to require blasting to break loose for quartz mill work. It is impossible to knock one of the pebbles from the mass only by piece-meal. The flour gold is diffused all through the cement, of which there is a mountain as colossal as the high peak north of town. The pebbles are as evenly distributed through the great mass as the gold, and it gives the same prospect on the apex as at the base, and the same as far in as they went as at the surface. The same character of pebbles and cement is found nowhere else. In short a like formation has never been discovered. It is literally a mountainous curiosity and how it was formed and whence it came are puzzling the minds of the intelligent and experienced prospectors who will return to work it next season. It is located in Wyoming, on the headwaters of Snake river. Mr. Plowman discovered it on his prospecting trips 20 years ago. — *Idaho Democrat*.

THE NEW NEVADA DISTRICT.—Hawthorne District, where the Lapanta ledge is located, is a vast pile of limestone, containing a network of ledges of decomposed quartz, and there seems to be no boundary to the golden area. In all directions, and in the most unpromising places, prospectors are finding deposits of the precious metal, and all orthodox rules of search have been abandoned. The theory which is now popular is that the gold is where it is found, and how and why it came there is left for future consideration. A toll road is already being projected, two town sites are beginning to show their pin feathers, and a stage line will soon be in operation. Already town lots have been sold on Water street and Fountain avenue in Lake City, and the real estate fever has taken a good start. Hawthorne has abandoned all interest in the silver question. The center of a triangle formed by three gold districts, its business men now only fear that gold values may depreciate. The Yellow Jacket mine to the southwest, the Gardener mines to the northwest, either sufficient to make things agreeable to people whose desires are within reasonable bounds, and the wonderful deposits in Lake district, directly east, make this a gold center of alarming activity.

INFORMATION FOR MINERS.—The weight of one cubic foot of solid quartz is 165 pounds; of broken quartz 94 pounds; of fine sand, dry, 100 to 115 pounds; of fine sand, wet, 82 to 90 pounds; of ordinary gravel, dry, 90 to 100 pounds; of ordinary gravel, wet, 80 to 90 pounds; of boulders not over six inches in diameter, 95 to 103 pounds; of gold, 1175 pounds; of water, 62.5 pounds; of ice, 37.3 pounds; of one gallon of water, 8.32 pounds. The estimated average quantity of ordinary ground worked per day of 10 hours, per man, by different methods is as follows: By pan, one cubic yard; by rocker, two cubic yards; by long tom, five cubic yards; by sluice, 15, and by hydraulic 100 to 1000 yards. The above statement of facts was furnished the Elk Mountain Pilot by Mr. M. A. Hawkes. It is valuable and should be preserved for reference.

THE RESERVATION.—The mining discoveries near Hawthorne are certain to bring about some change in the Indian reservation at Walker Lake. Large tracts of mountain containing minerals, and wood and water, are included in the reservation. These are utterly useless to the Indians, or, at any rate, not the least use is made of these resources by the Indians. Along Walker river, and included in the reservation, is rich, fertile land enough to support several times the number of Indians located there. Very little of this fine land is improved. The Indians wander up and down the railroad, lie around the towns and stations, beg or steal, but will not work. It is no kindness to these people to prevent the development of great mineral resources on ground utterly worthless to them. A change should be made in the Walker Lake reservation. — *Inyo Independent*.

PAPER PIANOS.—A German technical journal gives an account of an interesting experiment in piano making. The case is made entirely of paper instead of wood, so compressed that it can be highly polished. The color is a creamy white. The tone of this instrument is reported to be not loud, but very sweet. The sound is emitted, unlike the short broken note of the ordinary piano, is soft, full, and slightly continuous, resembling, somewhat that of the organ. This modification of tone is attributed to the evenness of texture of the compressed paper.

THE Butte papers are advising those seeking employment to stay away from Butte, as there is a vast surplus of unemployed men now there. Every mining superintendent has from 20 to 100 applications per day for work, which he cannot give. With all its immense industries, it is said "Butte cannot give employment to all the men in the Rocky mountains," and the presence of so many unemployed men during the winter is looked to with much concern.

Passing Events.

The signing of a deed giving several millions of dollars to found a technical educational institution in California, as was done a few days since by Senator Leland Stanford, of this city, is an event of prime importance to the educational interests of this State. Judging from the tenor of the endowment documents, the University will be one of wide scope, and is destined to accomplish much good.

The heavy rains of the past week have filled the ditches, streams and rivers. Although hydraulic miners cannot use the water, there are many miners who can, and who rejoice at its abundance. Of course river mining is put a stop to for the season.

The prospectors' occupation is about done for this year, as the snow has driven most of them to the camps. There is nothing of special moment to record from the mining fields aside from what we have referred to in our mining summary, on other pages of the PRESS.

Of the alleged 50,000 circulars sent out by the Board of Trade of New York to business men to ascertain the feeling in reference to the silver dollar, not a copy was received anywhere in Montana.

Timber Land and Mines.

The recent order of the Commissioner of the General Land Office concerning timber on the public domain, which puts a different construction on the timber laws from that accepted and acted upon during the past few years, is of great interest to the mining community. In the mining regions where large amounts of timber are required, it has been the custom to cut the trees on the public lands for this purpose. It has been considered that if the timber was used near where cut, and not made into lumber for shipping, the cutting was not illegal. In California, Nevada, Oregon and Washington Territory, an act of Congress allows the location of land chiefly valuable for stone and timber, when unfit for cultivation or mining. And this may be done on land not yet proclaimed and offered for public auction. No more than 160 acres can be taken up, and it must be paid for at a price of \$2.50 per acre. This Act (June 3, 1878) expressly specifies that after its passage "it shall be unlawful to cut, or cause or procure to be cut, or wantonly destroy, any timber growing on any lands of the United States, in said States or Territories, or remove, or cause to be removed, any timber from said public lands, with intent to export or dispose of the same." It even forbids vessels or railroads transporting any lumber manufactured from said lands.

There is a provision, however, in the Act that nothing contained in it shall prevent any miner or agriculturist from clearing his land in the ordinary working of his mining claim, or preparing his farm for tillage, or from taking the timber necessary to support his improvements.

As stated, this Act only applies to California, Oregon, Nevada and Washington Territory. Just now they are in trouble in Montana over the recent circular of the Land Office on this timber question. A petition is being signed around Butte, addressed to the Secretary of the Interior, asking that the order of the Commissioner be suspended until the people of Montana could be heard from. The document protests against any rules that will prohibit the cutting of timber upon public lands in Montana, to be used for mining, milling, smelting or domestic purposes.

The protest states that there are now in Butte and its vicinity about 20,000 people who are dependent for support on the mines of Butte. There is paid out by the mines of the camp, monthly, nearly half a million of dollars for labor, supplies and improvements.

There are now in operation, in Butte, eight quartz mills having 250 stamps, and six smelters and concentrating works with a capacity of 1000 tons per day. In addition to this there is near by the Anaconda smelter, the largest in the United States, if not in the world.

The Butte ore generally is not high grade, and must be worked as cheaply as possible. Most of the milling ore has to be roasted and the copper ore has to be treated by smelting and concentration.

For this reason large amounts of timber are required, and unless it can be obtained at reasonable rates the mining industry must come to an end. Large amounts of timber are also necessary to supply the needs of the people for domestic and building purposes.

The timber used for the purposes is taken from the public timber lands, which in this section are, as a rule, mountainous and have no possible value, except for the timber or as mineral lands.

None of the timber cut is exported from the Territory, but is used exclusively to sustain its mining industry and develop its resources, and for this reason the rule requiring each man to cut his own timber is unjust and should not be enforced.

Under the old rules which the people believed would be continued, they have built up the most populous mining camp in the world, but if the Government takes such action, as it is reported it may do upon the timber question, the labor is in vain, the capital is valueless, the mines must be shut down, the mills and smelters closed, business suspended, and from the most prosperous community for its population in the United States they relapse into the uncivilized wilderness which was found there a few years ago.

The Pioneer mill at Globe, Arizona, was burned down on Monday; loss, \$8000.

Instruction in Metallurgy.

While there is more or less instruction given in mining matters in Europe and in this country it has not been until of comparatively recent date that metallurgy has received the attention due it. Even now there are very few places where metallurgical students are properly educated. In fact, our books on metallurgy are by no means abundant, though the subject is one on which much information is needed and asked for. When it is remembered that the work of the miner must be supplemented by that of the metallurgist it would seem that wherever mining is taught metallurgy would receive due prominence. The advantages of technical education are now being more generally recognized all over the world. Metallurgy requires scientific knowledge, and practical work as well, and there are few fields where young men would find such chance of profit and advancement as in this. It is one of the professions that will pay, and which is not now over crowded.

A new school of metallurgy has been opened at the Birmingham and Midland Institute, and it is an important step in the technical teaching of England. At the opening of the school recently, Professor W. Chandler Roberts, chemist of the Mint, and Professor of Metallurgy at the Royal School of Mines, delivered an address, in which he deplores the fact that we appear to have imitated the systems of early metallurgists and alchemists in handing traditions and discoveries down to one or two pupils only. The greatest advances in theoretical metallurgy, he considers, were due to recent times, the result of individual and not collective teaching. It was not until Dr. Percy was appointed to the chair of metallurgy at the Royal School of Mines that systematic teaching was commenced.

The Royal School of Mines has trusted to elaborate lectures, and has devoted special care to a complete system of laboratory work. The *Ecole des Mines*, in Paris, adopts a system which is in the main the same, but the students visit and report upon works during their vacation—a plan Professor Roberts has endeavored to imitate since his appointment to the chair at the School of Mines, in 1880. Second, there is what may be called the system of Freiberg, as it is so well represented at the great school in Saxony, where the men study metallurgy theoretically, in lectures to which a somewhat limited laboratory course is added, the great feature of the instruction being the facilities the men have for spending a portion of each day in the Halsbrückner Hütte or the Muldner Hütte, these being the great works of the district in which the school is situated. And, finally, there is the system adopted in America, especially at the School of Mines, Columbia College, New York, and at the Massachusetts Institute of Technology at Boston, where, in addition to laboratory work as ordinarily understood, students carry out metallurgical operations, more or less experimentally, it is true, but, as an engineer would say, on a scale of nearly "12 inches to a foot."

It is somewhat difficult to compare the relative merits of these apparently distinct systems, because the conditions of the countries in which they are in force are so different. In London, Paris, New York and Boston the mining schools are situated at some distance from metallurgical centers. From an American point of view the distance of London from South Wales, Lancashire and Yorkshire must seem insignificant; but distance is not the only difficulty to be met. In England the works are not under Government control, and students therefore owe their admission to works to the generosity of the owners, which has hitherto been so liberally exercised that the absence of State influence has not been felt. On the continent the control of work by the Government enables students to visit the various establishments as a matter of right, and this fact has doubtless determined the situation of certain mining schools.

Although no strict comparison can be made, Prof. Roberts brings forward the following prominent points connected with the three systems: The Royal School of Mines was established at a time when the systematic teaching of metallurgy had been neglected. It was only natural, therefore, that extreme importance should be attached to laboratory work, and especially to researches having for their object the investigation of obscure points in metallurgical practice. There is, in fact, far too great a

tendency at the present day to lose sight of the importance, from an educational point of view, of having the teaching of students on a thorough knowledge of the chemical reactions upon which metallurgical operations must depend, and on rigorous and minute chemical analysis.

With regard to the Freiberg system, its chief merit appears to consist in giving the students broad views as to practical details, if it does not familiarize them with the real difficulties of metallurgical work. Surely, it may be urged, the frequent opportunities for seeing metallurgical operations must be of great value to the student; but consider how short a time a student, who is preparing for the higher branches of his profession, can possibly give to the purely theoretical work which he must get through. No system by which a student accompanies a demonstrator, or even a local foreman, to works, and only sees the successes and not the failures of other people's labors, really affords him adequate instruction.

Prof. R. H. Richards, of Boston, observes "that large charges cannot afford to spoil a furnace charge to show a student what happens from a little carelessness."

In the American schools of mines plant of sufficient power is provided to render it possible to concentrate by the ordinary dressing appliances no less than four tons of any given ore, and to treat the enriched product by suitable metallurgical process, adopting either "dry" or "wet" methods, or both combined, as the necessities of the case demand; and it may be added that the "plant" provided is sufficiently comprehensive to permit the adoption of very varied methods of treatment.

Leland Stanford Jr. University.

The papers and popular conversation during the last half year have been largely occupied with rumors and surmises about a grand educational institution to be established by Governor and Mrs. Leland Stanford to perpetuate the memory of their young son who died while the family were visiting Europe. Not until Saturday of last week was the public given full information of the grand and useful undertaking to which the Stanfords will devote their great wealth. On that day there was a meeting at Governor Stanford's house in this city of the Board of Trustees into whose hands he commits the management of the University which he will establish and equip. The property which has been deeded to the State for the purpose, has a present value of three and one half millions, and it is the general understanding that Mr. and Mrs. Stanford will farther contribute to the University until it receives an endowment of thirty millions or upwards: making it in fact their sole legatee in the place of the heir whose death has led them to bestow their whole wealth for the advancement of the people rather than divide it for the personal benefit of relatives.

The best use which can be made of great aggregates of wealth is to devote them to the comfort or safety or intellectual advancement of the people. There is a bright list of philanthropists, who, having been more fortunate than their fellows in amassing this world's goods, have so placed the rewards of their successful stewardship, that they remain for all time a blessing to their fellowmen. Many do this at their death, being unable to summon courage to part with their fortunes while living. We have always admired those rather, who, while still in health and strength, planned and carried out the philanthropic enterprises which their wealth secured. How wise for Governor Stanford, not only to give his money, but also many years of his life to the building up of the beneficent institution which he has planned.

There are all shades of opinion as to what should be the aims and methods of educational work. We find our own ideas changing as we grow older, and the conditions of public affairs seem to be changing. We do not profess to be especially expert in the philosophy of education, but it seems to us that the University planned by Governor Stanford, and upon the development of which he now enters with so much zeal, will approach nearer to the real needs of the people than any institution now in existence. The object of the University is thus described in the deed executed by Mr. and Mrs. Stanford to the Board of Trustees:

The nature, object and purposes of the institution hereby founded to be: Its nature, that of a University, with such seminars of learning as shall make it of the highest grade, including

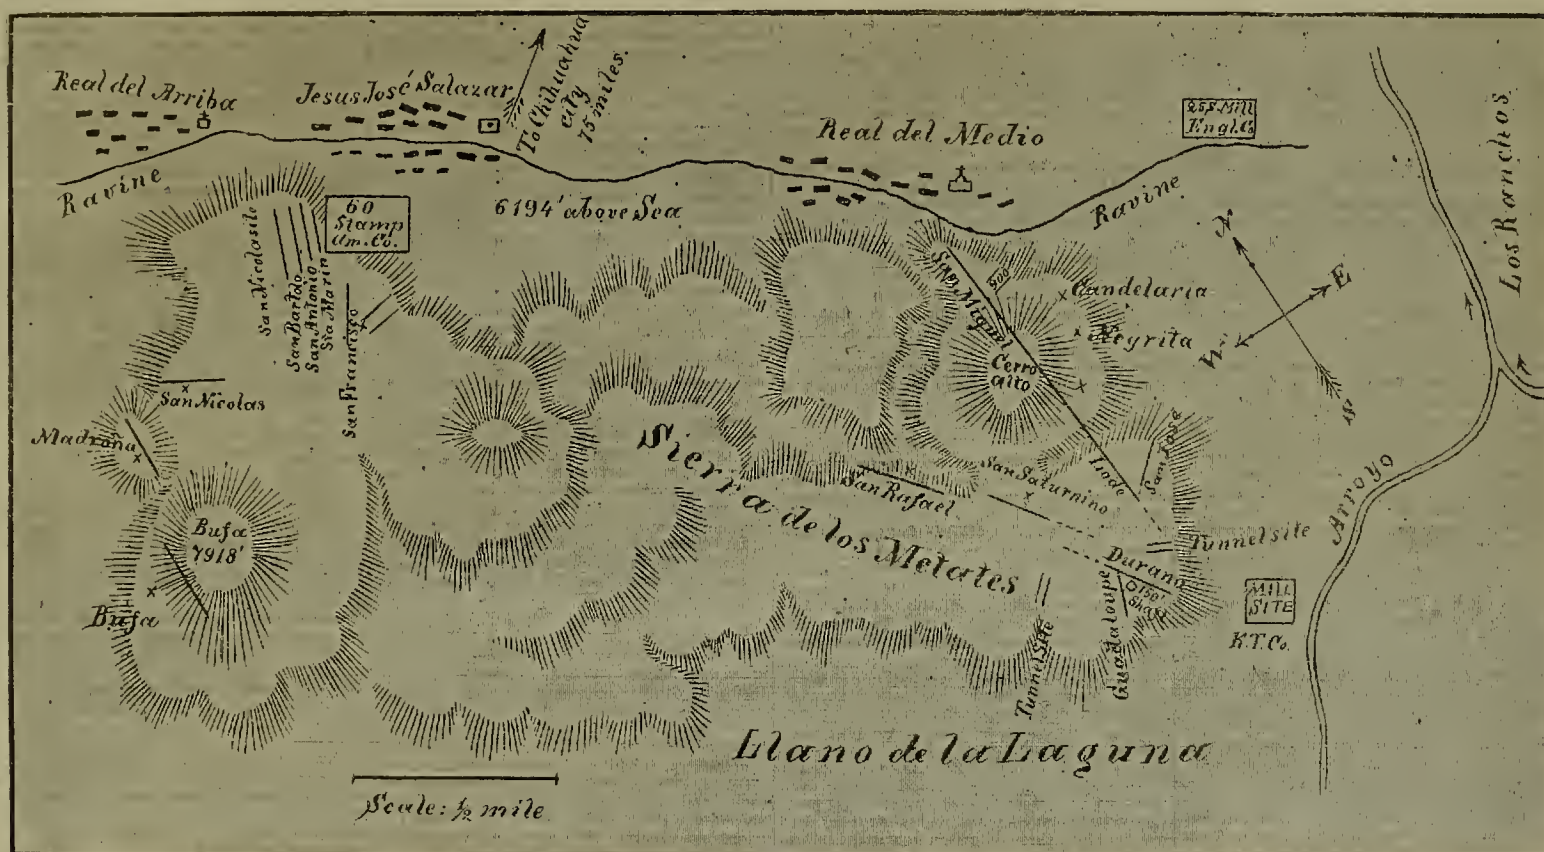

To establish and maintain at such University an educational system which will, if followed,

Out of these suggestions grows the consideration of the great advantage, especially to the laboring man, of co-operation, by which each individual has the benefit of the intellectual and physical forces of his associates. It is by the intelligent application of these principles that there will be found the greatest lever to elevate the mass of humanity, and laws should be formed to protect and develop co-operative associations. Laws with this object in view will furnish the poor man complete protection against the monopoly of the rich, and such laws properly administered and availed of, will insure to the workers of the country the full fruits of their industry and enterprise. They will accomplish all that is sought to be secured by the labor leagues, trades unions and other federations of workmen, and will be free from the objection of even impliedly attempting to take the unauthorized or wrongful control of the property, capital or time of others.

[Written for PRESS by W. H. PURDIE.]

A few items from this, one of the oldest and most noted of silver mining districts in the Republic of Mexico, if worthy of a space in the columns of your valuable journal, might not prove uninteresting to its readers of the mining community. Cuahuiraichic is located in Lat. 28° 61' N., Long. 6° 54' W. Mex., 75 to 81 miles south of west of the city of Chihuahua, in the loftiest part of the mountain chain of the Sierra de los Metates. This mountain chain is 100 miles east of the main range of the Cordilleras or the Sierra Madre, and 439 feet lower. The Sierra de los Metates is of similar formation to all of Northern Chihuahua. cretaceous fossiliferous.

Transportation facilities and all other resources conducive to the mining interests of this district, soon to rank with the best of Mexico, cannot be excelled in any country. We hail with pleasure the successful issue of these

CUSHUIRIACHIC MINING DISTRICT, CHIHUAHUA, MEXICO.

The merely physical wants of civilized man are not much greater than those of the savage, but his intellectual wants are bounded only by his capacity to conceive. His wants, therefore, will always depend upon his advancement in civilization, and the demand for labor will be measured accordingly. The rapidity of the communication of modern thought and the facilities for transportation make the civilized

Some two years ago the North Mexican Silver Mining Company, of London, entered the field and purchased the "Saturnino," "Durana"

THE inconvenient consequences of the withdrawal of Belgium from the Latin Monetary Union are beginning to be felt in France. In a few weeks the Belgian silver five-franc piece will cease to be a legal tender. The total loss on all the repudiated money circulating in France will exceed 30,000,000 francs.

MECHANICAL PROGRESS.

Wrought-Iron Castings.

Something New and Valuable in Metallurgy.

For the past year or two occasional allusions have been made in several technical journals, both in this country and Europe, in regard to a new process in metallurgy by which castings of wrought-iron could be produced as successfully as those of steel or cast-iron. Of late more authoritative and definite statements have appeared. In May last a paper was read at the meeting of the Iron and Steel Institute of London by Mr. Nordenfeldt, an eminent English machinist, in which the new process was described and fully endorsed by him. Such an authoritative declaration that wrought-iron, with all its desirable qualities, could be cast in a commercially practicable manner, elicited much attention from the members of the association and from all others engaged in iron manufactures. Sir Henry Bessemer, who was present and listened to the reading of the paper, is said to have expressed the opinion that the invention was of fully equal value to that of his own, known as the Bessemer process of converting cast iron into steel.

The manner in which the results were obtained at an experimental furnace built in Worcester, Massachusetts, are described in the *Boston Journal of Commerce* as follows: "The furnace is of peculiar construction, and, as the first successful attempt to use liquid fuel for this purpose, merits description. It is of iron, about five feet long, two high and three wide, and is divided into three compartments, each large enough to contain two crucibles, each holding the iron. At one end of the furnace there are three V-shaped troughs, about three inches deep. Into these troughs crude petroleum is fed from a tank some distance removed. Being ignited, the flame is turned into the furnace by the draft of this chimney. It then passes down a narrow chamber, constructed of fire-brick, and enters the first crucible compartment through an opening near its bottom, uniting at the same time with a stream of air from an atmospheric conduit in this bottom of the furnace. The flame is most intense, and completely envelops the crucibles. From the first compartment it emerges at the top on the further side, and enters the second compartment, surrounds the crucibles therein contained, and passes through an opening at the bottom of the third compartment. After surrounding the crucibles therein contained it passes out near the top and into the chimney. It is obvious that the degree of heat to which the successive crucibles are subjected is of varying intensity, the severest heat being in the first compartment. This, which was at first thought objectionable, is found to be an advantage, though it necessitates more labor. Each crucible in its turn occupies each compartment, and a more perfect combustion is obtained thereby. When crucibles No. 1, or those at the front, are taken out to be poured, No. 2 takes their places, No. 3 taking the place of No. 2, and newly charged crucibles being placed in the compartment vacated by crucible No. 3. The intensity of the flame is regulated by a very primitive but effective method, it being the moving of a fire-brick over an opening in the first air duct. The compartments are each covered by a slab of fire-clay, which contains a circular opening for viewing the progress of the combustion. The crucibles remain in the furnace from two to three hours. Then the two in the first compartment are taken from their fiery path and carried to the mold containing the pattern, into which the glowing mass is poured directly from the crucible. From this time it is treated like ordinary castings.

"The molten iron is much more liquid and fluent than ordinary cast-iron. It seems to run with the facility of water. On this account it is practicable to produce, by the new process, castings solid and fine beyond example. There are some features in the process not yet disclosed to the public, though there are several patents, each of which is considered essential to the success of the new method."

The castings can be hammered, welded, elongated, filed, etc., as easily as ordinary bar iron, and is said to be from 20 to 25 per cent stronger than good wrought-iron. The melting by the furnaces above described is very rapid and perfect, requiring less than half the time of ordinary melting of steel or cast iron.

To recount all the uses to which castings could be put would be simply a rehearsal of one-half or more of all iron articles now in use. It is said that Sir Henry Bessemer, on seeing the articles cast by this process on exhibition in London, remarked: "This is impossible, still it is a fact."

The Process in this Country.

The process has been essayed in Worcester, Mass., and, it is said, with complete success, under the direction of some Swiss engineers, who had learned the same from the inventor. The parties who have been experimenting there have secured the right for the United States.

Brief History of the Invention.

The journal from which we have quoted above gives the following brief history of the invention, as narrated by Mr. Ostberg, one of its chief promoters: For several years a Swedish engineer and mechanic, then in Russia, had been experimenting in this direction. Having succeeded to his satisfaction in the laboratory, he rather prematurely endeavored to get his invention adopted by the public.

When it became necessary to manufacture on a scale sufficiently large to meet the requirements of commerce, many defects and hindrances disclosed themselves. After it had passed through a varying fortune for some months, Messrs. Faustman & Ostberg, of Stockholm, became acquainted with the situation of affairs, and, realizing the great importance of the invention if it could be made practicable, they devoted much time to an effort to perfect it. About a year since they achieved a result which conformed to their desires. They immediately converted their malleable iron shops into works for manufacturing the new product, which is termed "Mitie," adopted from the Latin adjective, having the significance of ductility.

Mr. Nordenfeldt acquired the right to use the invention throughout the greater part of Europe, and Messrs. Faustman & Ostberg secured the right for Sweden, and also for the entire United States. It was under their direction that the experiments at Worcester were undertaken.

ASBESTOS FOR PISTON AND VALVE ROD PACKING.—Asbestos is a substance which can readily be manufactured into ropes, etc., which cannot be changed except by a high degree of heat, and is not effected by acids nor grease. These qualities, in addition to its cotton-like consistency, especially adapt it to the purposes of packing all kinds of rods and joints which are exposed to the action of steam of either a high or low temperature. As a piston or valve rod packing, for high pressure, there is nothing superior to it if well managed. It is found on sale at most all places where engineers' supplies are kept, in the form of rope, for piston and valve rod packing, and in sheets for steam chest and pipe flange joints. When used for piston and valve rod packing it should be well lubricated with a compound composed of equal parts of plumbago and tallow, and when placed in the gland around the rod great care should be used that it is not screwed up too tightly. This packing, if the rod is lubricated every two or three days with the plumbago and tallow compound, will outlast any known substance for this purpose. To prepare asbestos for joints, cut to the required size, and then paint one side with red lead, and the other cover with plumbago, so that if it becomes necessary to separate the joint after being made, it can be done without injuring the packing. Steam chest joints, which are so often separated for this purpose of valve inspection, when made of this material, and in this manner, will last for years without removal.

WIRE AND ITS USES.—This inelastic material that has been drawn out into a metallic thread has not only been woven, braided and twisted into almost every thing in the metallic line but has at last endured the tortures of the knitting machine and appeared in the form of a door mat, where the heavy stitches of wire make all the intersections and looped spacings desirable for a serviceable mat, where the hardest ice or snow-hall can be easily removed by them. In no part of our economy are we divorced from wire. It is our slave, and an ever-present master. Sleeping, we repose on wire mattresses. Eating, we see food which has passed through sieves, and which is sheltered from insect appetite by wire covers. Calling, we pull wires to ring curled wire bells. Traveling, we are conveyed by cable or electric railways, hoisted by elevators hung on wires and hurried over wire bridges. We announce our coming by telegraph or telephone wires, and we thread our way by night through streets lighted by means of electric cables. Across our fields are strung thousands of miles of barbed wire. Our clocks are set by wires, our watches run by wires, our hooks are etched by wires, our pictures hung by wires, and our politics managed by wires. Forty years ago there was not a telegraph office in existence. To-day they number over 60,000. Ten years ago the telephone was not in existence. To-day there are 330,000 in use in the United States alone.

THE BEST WELD.—Mr. Purvis, an English engineer, read a paper before the Institution of Naval Engineers on large forgings. Speaking of the different kinds of welds, he gave the preference, for heavy work, to the scarf weld, and considered the long V weld next best. He submitted some large specimens of welds, made by the use of sledge hammers, sows and the steam-hammer. Upon trial all of the welds broke at a red heat, by being bent, except the one made under the steam-hammer which was repeatedly bent forward and back till black hot, and then broke elsewhere than at the weld.

TESTING BELTING LEATHER.—M. Eitner proposes the following simple method of determining the value of leather employed on belting. A cutting of the material about .03 of an inch in thickness is placed in strong vinegar. If the leather has been thoroughly acted upon by the tannin, and is hence of good quality, it will remain, for months even, immersed without alteration, simply becoming a little darker in color. But, on the contrary, if not well impregnated by the tannin, the fibers will quickly swell, and, after a short period, become transformed into a gelatinous mass.

LOOK WELL TO THE BEARINGS of your shafting, engine and machine. Sometimes 25, 30, 40, and even 50 per cent of your power is consumed through lack of good oil.

SCIENTIFIC PROGRESS.

The World in Which We Live.

The above words are very significant; they are reminders to many of a varied experience, that is fraught alternately with joy and hope, and the woes and sorrows of life; such, in fact, as constitute the common realities of life.

Upon the world's grand stage the generations come and go, like a mighty army marching on to victory or death, with little apparent reason for their coming or departure. To-day, while we are so eager in our pursuits, we are walking swiftly in the tracks of hygone generations. All the chambers of life are hung with tapestry wrought by their fingers, while the cadences of their last farewell still faintly echo in every passing breeze, and linger on every distant hill and wave. The mighty stream of time is swiftly bearing us on to a common destination; we may be wrecked, but we cannot be delayed. At every pulsation of the heart a human being is called from the shores of time to the realm of evermore. Nor do they go alone; high hopes of human hearts have gone with them. Many a rapturous theme has perished with its author. The fresh dust is cold on many a breast that burned with fires that seemed immortal.

While I now write and turn to view our brief sojourn here, mighty movements are agitating the society of nations. The mechanism of human industries is no less active than it was when moved by the hands that lie nerveless in the shades of gone-by years. The movement of terrestrial affairs, gathering all the forces of life through natural agencies, and sending them through millions of living beings of every order, carries within itself the origin and destiny of nations as counterparts of a grand universal whole.

From the experience of mankind we are furnished with a record of failures and successes; from it we learn that all the doors of the world do not open into success and happiness, but many are the entrances into the avenues of crime and wretchedness, and the careless and unwary will naturally and unconsciously enter them. It takes no effort to enter the wrong road of life. All along are thousands of wrecks, that with precaution and timely effort might have been avoided, and the unfortunate thus wrecked might have been blessings to the world. All knowledge that would enrich the mind and make us useful, all those higher mental qualities that would refine our lives, and all those spiritual attainments that would give equilibrium to our powers—an equilibrium that constitutes happiness—are set forth as prizes to be obtained by earnest and unflinching effort. By all the motives that can be brought to bear our engagement in this effort is solicited. By the woes and wrecks of life we are warned of the many dangers that attend its pathway. Let us imitate the wise who have taken advantage of the favoring tide, and have been borne to success and happiness.—T. N. Curtis in *Phrenological Journal*.

BENEFICIAL INFLUENCE OF RELIGION.—The worst kind of religion is no religion at all; and those men, living in ease and luxury, indulging themselves in the amusements of going without religion, may be thankful that they live in lands where the gospel they neglect has tamed the heartlessness and ferocity of the men who, but for Christianity, might long ago have eaten their carcasses like the South Sea Islanders, or cut off their heads and tanned their hides like the monsters of the French Revolution. When the microscopic search of scepticism, which had hunted the heavens and sounded the seas to disprove the existence of a Creator, has turned its attention to human society, and has found a place on this planet 10 miles square where a decent man can live in decency, comfort, and security, supporting and educating his children unspoiled and unpolluted; a place where age is revered, infancy respected, manhood respected, womanhood honored, and human life held in due regard; when sceptics can find such a place ten miles square on this globe, where the gospel of Christ has not gone and cleared the way and laid the foundations and made decency and security possible, it will then be in order for the sceptical literati to move thither and there ventilate their views. But so long as these very men are dependent upon the religion which they discard for every privilege they enjoy, they may well hesitate a little, before they seek to rob the Christian of his hope and humanity, of its faith in that Savior who alone has given to man that hope of life eternal which makes life tolerable and society possible, and robs death of its terrors and the grave of its gloom.—*Science*.

THE HIGHER STUDIES.—Although there has been a great deal of discussion on the point, it has never been definitely settled whether the dead languages ought not to give place to the living languages in the educational course of our higher institutions of learning. There are good arguments from high authorities on both sides. The fact would appear to us that the studies should be adapted to the profession or occupation which the student intends to follow in after life. If he is to be a lawyer or physician, or historian, it would be well to have a knowledge of Latin. Greek seems not to be of so much importance. To an English-speaking scholar, however, whose life is marked out for business pursuits, a thorough knowledge of the English language will serve him well. To be

versed in any other language than his vernacular and deficient in that would expose him to merited ridicule. Sir Lyon Playfair has been giving this subject some study. At a recent British Association meeting he imparted this information: At the Oxford and Cambridge certificate examinations of last summer 703 boys passed in Latin and 673 in Greek, but only 131 in any and all the branches of science. There were only 263 proficient in French and 94 in German, while, most deplorable of all, the number of those who passed in English did not rise above 113. It may be inferred, then, that more than six times as much attention had been paid to Latin as to English; and that all the sciences had been esteemed of less than one-fifth the value of Greek!

PREDICTING TORNADOES.—Great progress has been made within a few years in the study of storms. William A. Eddy, the reporter of the Signal Service Department, has issued the following circular: The attention of Congress is called to the fact that some of the terrible loss of life and property due to tornadoes can be averted. In 1882, Prof. T. B. Maury asserted what was then the fact, that the prediction of a tornado was a triumph yet to be attained by the science of meteorology. In less than two years from that time some predictions of tornadoes were successfully made by Lieutenant John P. Finley, of the Signal Service. The percentages of verified predictions is steadily increased by knowledge of the average conditions preceding each series of tornadoes, thus making the predictions more definite and local with each succeeding year. Already the predictions of safety for the day are effective. Of 3228 predictions unfavorable to tornadoes, made in 1884, 3201 were verified, and of 38 predictions that tornadoes would occur, made in April and June, 1884, 18 were verified. Of 19 predictions that tornadoes would occur, made in June and July, 1885, 15 were generally verified. When tornadoes were predicted, in no instance did violent storms fail to occur, either hurricanes, tornadoes or hail.

MAN FORMED OF CONDENSED AIR.—Chemistry has demonstrated that man, this very highest specimen of the animal kingdom, is really formed of condensed air—or solidified and liquefied gases—that he lives on condensed air as well as uncondensed air, and by means of the same agent moves the heaviest weights with the velocity of the wind. The strangest part of this matter is, however, that thousands of these beings formed of condensed air, and going on two legs, occasionally, and on account of the production and supply of condensed air which they require for food and clothing, or on account of their honor and power, destroy each other by means of pitched battles in condensed air; and, further, that many peculiar powers of the bodiless, conscious, thinking and sensitive being, housed in this tabernacle of condensed air and moisture, to his result, simply, of its internal structure, and the arrangement of its particles or atoms; while the science of chemistry supplies the clearest proof that so far as concerns this, the ultimate and most minute composition as well as structure, which is beyond the reach of our senses and power of science to determine, man is, to all appearance, identical with the ox, sheep, bird or fish.

THE MOON AND ITS SIGNIFICANCE.—Prof. Richard A. Proctor, the English astronomer, says the moon is the most interesting of all the heavenly bodies. It has been particularly serviceable in the proof it affords of the law of gravitation. It proves, too, what the world has been in remote ages of the past, and what it will be in remote ages to come. Its most significant service to man has been as a measurement of time. The only perceptible effect which the earth has upon the moon's course is that of attraction, by which its route in space is slightly deviated. From the moon's present condition we may inform ourselves of the course of all planetary life. There is every reason to suppose that our present condition was at one time hers; that she possessed an atmosphere, water, animal and vegetable life. That has now passed away. Her surface is a sterile, rocky mass. The atmosphere has gone, or nearly so, and the seas are dried up. The same process is going on with our earth, and a similar result will eventually ensue, but by reason of the greater bulk of our planet effects produced in 10,000,000 years in the moon will require 60,000,000 with us.

FOSSIL INSECTS.—In 1879 only 103 fossil insects from the carboniferous rocks of the whole world were known, but during the last five years a great number have been discovered, including 1400 from Commeny, France, a few from Saarbrück, Kleinopitz, Lugau and other continental European mines, and a very considerable number from the mines in this country.

GEOLOGICAL SURVEY OF MEXICO.—The Mexican Government has resolved on undertaking a geological survey of the whole of Mexico, as far as practicable, and they have appropriated \$10,000 for the preliminary expenses. A survey on an extensive scale cannot fail to have an important influence in developing Mexican mineral resources.

THE "BOGS" OF IRELAND.—Surveys and careful measurements show that peat bogs cover about one-seventh of the surface of Ireland. Some of these bogs are supposed to represent fully 20,000 years' growth.

The Inventive Age.

People are quite too much inclined to look upon inventors as an impractical visionary class of persons. This is the tone of nearly every leading inventor for the last century and more. The history of Franklin, Fulton, Watt and many others of their contemporaries fully corroborates this assertion.

Coming down to a more recent period, he is not familiar with the discouragements and trials of Howe, ere he made the sewing machine a success? Singer also met with the same experience, and it is said that while he was himself personally and laboriously working upon his famous experimental machine, his fellow-workmen in the shops, turned away from him with disdain as a "crank" trying to work out an impossibility. Westinghouse, and even Thomas and Gilchrist, and Edison, whose names are now world famous, were each in their turn objects of ridicule and abuse.

The wonderful development of the use of steam could hardly have been foreseen by Watt when he patented his first steam engine in 1769, but it is a noteworthy fact that away back in 1750, when he was but 14 years of age, he constructed an electrical machine, thus utilizing a force that seems now likely to supersede steam to some extent. Watt was an inventive genius, and his early discouragements and trials were such as seem to fall to the lot of others of the inventive class. Unlike many of his predecessors and successors, however, he lived to gather and enjoy the fruits of his labors. As the inventor of the steam engine, his name stands enshrined among the noblest benefactors of the human race, and in no part of the world has his thought and the product of his hand been utilized to serve a greater variety of purposes than in progressive America.

We have before us a paragraph, the authorship of which is unknown to the writer, but which is so much in point that we transcribe as follows:

"The man who strives to perfect an invention, whether successful or not, is entitled to the commendation of his fellow men. We have never sympathized with those who speak sneeringly even of that much despised class of inventors, those who have striven to solve the problem of perpetual motion. Mistaken and erratic as they may be, they are engaged in a line of duty which is, to say the least, honorable and elevating. Thousands of inventions there are to day that the world calls valueless, which, were they placed in practical hands, would prove most useful and beneficial, and a source of wealth to the owners.

"Inventions, as a general thing, are an innovation on present customs or modes, and are therefore a step in advance of present thought. A century since, had any one suggested that one could stand in his own home and hold converse with a friend fifty miles away, he would be thought to be talking nonsense. Had any one at that time said that the mail would be carried from New York to Chicago in a day, he would have been considered equally as foolish. The prediction that messages could be sent on lightning's wing beneath the ocean from this continent to the Eastern continent would have been hailed with ridicule. These inventions were steps far in advance of the thought or knowledge of those days. It does not militate against the greatness of the discoveries that made all these things possible that the dull brain of the masses could not comprehend them until they were practically displayed to the world. The further he is in advance of the present thought or knowledge of the masses, the greater will be the opposition which the inventor will have to overcome before he will attain a just recognition of his labors.

"A great inventor must be a man of independent thought, a man of nerve and courage, a man of hopefulness and of determination. Many an inventor has been turned back, even when his feet were pressing the threshold of a great discovery, because he had not courage to stem the tide of opposition which he was encountering. Many a practical invention has been dropped before completion because of the inventor's discouragement and lack of push and determination.

"It is a surprising thought, when contemplating what invention has done for the progress and civilization of the age, that inventors meet with such a tardy recognition of their works. The wonder is that they are not held in higher esteem. The world could afford to pension its Stephensons, its Morses, its Bessemers, its Edisons, and its Bells. It has erected statues to some of these, and it can afford to erect statues to all its noted discoverers. In olden times men of scientific attainments were held in high esteem. Why ought they not to be held in a like high estimation to-day?

"We grant that the names we have given above are so held, but there are untold thousands of names of inventors of useful things, valuable and indispensable to the world, that should be placed in glowing letters on the scroll of fame. Our inventors need encouragement when they are alive, not after they are dead. Men do not work simply to gain a fitting epitaph. Their needs are in the present, and the earlier the world recognizes and applauds their work, the better will it be for them and the inventive art."

In San Luis Obispo county \$2,000,000 has been loaned by San Francisco capitalists on real estate.

USEFUL INFORMATION.

THE DETECTION OF FATTY OILS IN MINERAL OILS.—Friedrich Lux founds his method upon the different behavior of the fatty and mineral oils, when heated with potash, potassium, soda or sodium. For instance, rape oil, when heated with potash or soda to a high temperature saponifies—stirring or shaking promoting the reaction. At a temperature of 250° C. rape oil gelatinizes with potash or soda in five minutes; after 15 minutes the oil turns brown and solidifies to a buttery mass. On the other hand, mineral oils treated in the same way, become darker, but do not alter their state of aggregation. **A. Preliminary Test:** Detection of larger quantities of fatty oils (about 10 per cent or more). To about 5 c. c. of the oil under examination in a test tube, is added a small piece of sodium hydrate, the liquid heated directly over the flame to boiling, and kept boiling for about one or two minutes. Larger quantities of fatty oil are detected by the peculiar empyreumatic smell given off, and by the solidification of the liquid on slightly cooling. If a negative result is obtained, one proceeds as follows: B. The detection of smaller quantities of fatty oils (two per cent or less). Two middle sized beakers are taken, of which the one can be so far pushed into the other as to leave a space about 1-2 cm. between the two. Into this larger beaker is brought enough paraffine to bring its surface half way up between the sides of the two beakers. The inside beaker is also filled with paraffine to the same height. A paraffine bath, constructed in this way, cannot be overheated. The thermometer, hung in the inner beaker should be kept at about 200-210° C. Two test-tubes are now filled with a c. c. of the oil; to the one is added a few shavings of potassium, to the other a stick of potassium hydrate, so that the latter stands about one cm. above the surface of the oil. The two test tubes are placed in the bath and the time noted; after 15 minutes they are taken out and allowed to cool. If the mineral oil contains as much as two per cent fatty oil, it solidifies in one of the two test-tubes, generally in both, to a tough jelly.

A NEW USE FOR ASBESTOS.—In the processes connected with the dyeing and printing of cotton cloth, it is frequently necessary to hang the fabric in loops from parallel rods for the purpose of exposure to steam, air or ammonia. In order that the cloth should hold upon these rods without slipping or being strained, it is necessary to wind rope or strips of cloth around the rods; but this only mitigates the difficulty without accomplishing its removal; for the heat and corrosive action of the vapors rot any covering in a few weeks, and the first notice of any deterioration is generally the appearance of small pieces of roll covering among the cloth in process of finishing. Recently, asbestos rope and asbestos cloth have been used for this purpose, and prove to be very durable. Larger ropes of this refractory material have been used for the transmission of power over places exposed to heat.

THE WORK OF WINDMILLS.—In an article on windmills the *Scientific American* says: "An 8½ foot wheel will raise 3000 gallons of water daily a distance of 25 feet. Its first cost, including the pump and a plain tower, is about \$150. A 10-foot wheel will raise about 9000 gallons of water a day a like distance and cost about \$180, including the appurtenances above mentioned. A 12-foot wheel will raise 16,000 gallons of water a day, the above distance and cost, with the same appurtenances, \$210. So up, from 14 to 16, 18 to 20 feet diameter of wheel, until we reach a 25-foot wheel, which costs about \$1200 and will raise 100,000 gallons of water daily the specified distance.

HOW FIRE MAY BE CARRIED IN COTTON.—Edward Atkinson, of Boston, says: "Fire lurks in a cotton bale for weeks. The cotton which was injured somewhat over a year ago in Bedford, Me., was moved to South Boston for sale. The fire broke out again more than once while it was at South Boston being made ready for sale. It was then sold at auction. The fire broke out again in one parcel while it was on the cars being carried away, and in another parcel after it had been received at a factory where it was to be used. The latest outbreak was, I think, 30 days after the original fire."

ELECTROPLATING ON WOOD.—A novelty in silver is the discovery of a process of electroplating with silver upon wood, and its adaptation to handles of all kinds, including umbrellas, canes, carving-knives, etc. The silver is thrown upon the wood by a process which has proved extremely difficult in practice. The deposit of silver, of course, follows all the peculiarities of the wood, and the ordinary handle is simply garished in almost ineradicable silver. The special advantage is in the variety of designs that may be produced.

TO PREVENT THE CRACKING OF WOODEN FAUCETS, ETC.—Put the articles in melting paraffine and heat them there at a temperature of 212° F., until bubbles of air cease to escape from the wood. The whole is then allowed to cool to about 120° F., when the wood is taken from the bath and cleaned from the adhering paraffine by rubbing with a dry piece of cloth.

SOLDERING FLUID.—Some of the soldering fluids are injurious to tools and also to parts

that have been laid on the bench where such fluids have been used. The following recipe will do the work as well and will not rust and tarnish any more than water would. Take two ounces alcohol and put it into a bottle, and add about a teaspoonful of chloride of zinc and shake until dissolved. Use it in the same manner as the muriate of zinc, or muriatic acid and zinc. It has no bad smell.

BY THE ROAD OR IN A DIRECT LINE.—Alexander Cook, blacksmith, of Queens, L. I., covenanted when he sold his smithy to John W. Booth not to work within three miles of the shop. Cook went to work at a place which was more than three miles by the road, but less than three miles in a direct line. A lawsuit resulted and Judge Barnard decided constituted a breach of the covenant, as the words "within three miles," mean with that distance as the hec lios, and not as the road hands. Cook will now be liable to arrest for contempt.

MECHANICAL AID TO RIFLE PRACTICE.—Four hundred steel targets are being made at the Rock Island Armory. They are made to represent a soldier in three positions, and are covered with cloth (uniformed). In practice they will be placed in squads, platoons, companies, and various other forms in which soldiers move in an engagement. The practice will commence at a range of 250 to 300 yards, and be gradually increased to long distances.

TO RENDER RANCID LARD SWEET.—Chloride of soda will render rancid lard perfectly sweet. Put three ounces of chloride of soda into a pail full of hot water, and then put in the lard and boil the two together for an hour or two. When nearly cold, the lard is taken off and afterward boiled up. "The color is restored to an alabaster white, and the lard will be as sweet as a rose in June."

CONVENIENT POSTOFFICE WEIGHTS.—A silver dollar weighs nearly an ounce. Hence any letter not heavier than a dollar can go for a single two-cent stamp. A five-cent piece added will give the ounce. If you have not the silver dollar, five nickels and a small copper cent will give an ounce.

CLOVES AS MOTH EXTERMINATORS.—Whole cloves are now used to exterminate the meretricious and industrious moth. It is said they are more effectual as a destroying agent than either tobacco, camphor or cedar shavings.

TO CLEAN BRASS AND STEEL.—For brass: powder rottenstone, put it into a pint of water, add a teaspoonful of sulphuric acid, apply, then rub off and polish with whiting. For steel: emery powder mixed with turpentine.

GOOD HEALTH.

The Development of the Heart.

The *Hamburger Nachrichten* has recorded the observations made on the above subject by the late Dr. Benecke, of Marburg. According to these investigations, the greatest and most rapid growth of the heart takes place during the first and second years of human life. By the end of the second year its bulk is said to be exactly double what it originally was. Between the second and seventh years it is again almost doubled. A slower rate of growth now sets in until about the 15th year, the augmentation of volume during the intervening seven or eight years being only about two-thirds. In the period of maturity which now approaches, the growth of the heart again makes progress, the increase keeping pace with the advance toward maturity of the other portions of the system. Thus, as compared with its size at the age of 15, two thirds have been added by the age of 20. After the twentieth year the rate of development again becomes slower, but an increase in volume is perceptible up to the fiftieth year. The annual gain in bulk during that period is supposed to be about .061 of a cubic inch, and the maximum volume thus attained is estimated at from 16 to 17 cubic inches. Growth ceases after the fiftieth year is passed, and a slight diminution in the size of the heart ensues. This is regarded as a part of the general effects of approaching old age. As to the comparative size of the heart in males and females, it is stated that in childhood there is no difference of any note. When maturity sets in the male heart develops more than that of the female, and the difference of from one and a half to two cubic inches thus established is said to be maintained throughout the remainder of life.

DEPTH OF SLEEP.—Two of Vierordt's pupils, Moninghoff and Piesbergen, have made the depth of sleep the subject of an investigation. They worked upon the principle that the depth of sleep is proportional to the strength of the sensory stimulus necessary to awaken the sleeper—that is, to call forth some decisive sign awakened consciousness. As a sensory stimulus they made use of the auditory sensation produced by dropping a lead ball from a given height. The strength of the stimulus was reckoned, in accordance with some recent investigations of Vierordt, as increasing, not directly as the height, but as the 0.50 power of the height. For a perfectly healthy man, the curve which they give shows that for the first hour the slumber is very light; after one hour and 15 minutes the depth of sleep increases rapidly and

reaches its maximum point at one hour and 45 minutes; the curve then falls quickly to about two hours and 15 minutes and afterwards more gradually. At about four hours and 30 minutes there is a second small rise, which reaches its maximum at five hours and 30 minutes, after which the curve again gradually approaches the base line until the time of awakening. Experiments made upon persons not perfectly healthy, or after having made some exertion, give curves of a different form.

WHY DRUNKEN MEN ARE NOT INJURED BY FALLS.—One sometimes sees a drunken man pitched violently from a horse, and when the bystanders rush to the spot expecting to find him dead, they are astonished to find that he has been little injured. In his "Scrambles Among the High Alps," Leslie Stephen tells the story of a guide who, while drunk, fell over a precipice so deep that a fall over it seemed almost certain death, and who yet sustained little injury. Stephen accordingly gives his readers the advice either not to fall over a precipice, or to get thoroughly drunk before doing so. The reason of this immunity is that the nerve centers are so paralyzed in the drunken man as not to be affected by the shock of the fall, which, in a sober man, would have acted upon them so violently as to stop the heart, arrest the circulation and cause instant death.

BAKED APPLES IN SEASICKNESS.—If ever you should be in a position to advise a traveler going on a sea voyage, remember that there is some mysterious service done to the hitherto system, when it is shaken, by baked apples. Noticing that they were produced on board the Cuba every day at lunch and dinner, I thought I would make the experiment of always eating them freely. I am confident that they did wonders, not only at the time, but stopping the imaginary pitching and rolling after the voyage is over, from which many good amateur sailors suffer. I have hardly had the sensation at all, except in washing of a morning; and at that time I still hold on with one knee to the washing stand and could swear that it rolls from left to right.—*Letters of Charles Dickens.*

FULL BREATHING.—We have always maintained that the most important agent for the preservation of health and the cure of disease is a full and constant supply of pure air for the lungs. All the plans for systematizing exercise by combining it with proper pleasures should be encouraged. Horseback riding, walking, bicycling, foot-racing, and athletic sports are hardly less valuable for the increased quantity of air that they compel us to consume than for the exhilarating and healthful effects produced in our minds. In order to be of real value, exercise should be regular and, if possible, in the open air, and sufficient each day for the wants of the system; but never excessive. Extremes are always dangerous.

UNCLEAN HANDS.—Everybody's hands, it appears, are always more or less dirty. In the *Gazetta Medica Italiana* Dr. Forster says that after the most diligent washings and brushings with soap and water and rinsings with carbolie acids and other disinfectants, the hands remain so impure that, upon touching them to sterilized gelatine, micro-organisms were speedily developed. The doctor found, indeed, that on rinsing the hands with a solution of 1 to 1000 of corrosive sublimate they became "scientifically cleansed" for the time, but that in wiping them upon a towel not previously disinfected they returned to their sad condition of uncleanness.

THE EUCALYPTUS OVERESTIMATED(?).—Dr. Bonavia, of the Lucknow Horticultural Gardens, has but little faith in the statements as to the suitability and value of the eucalyptus globulus in swampy and marshy districts. The results of his experiments with the tree confirm the unfavorable results that have also been obtained with it in Italy, and he is surprised that it should ever have been deemed fitted to discharge the efficacious and salutary functions that have been so universally claimed on its behalf.

CAUSE OF RED NOSES.—Why is a drinker's nose red? is answered by Dr. Johnson, of Washington, D. C., who says that the drinker's heart beats about 13 times oftener than the heart of one who does not use liquor. The arteries, in consequence of this increased heart action, carry the blood to the nose quicker than the veins carry it back. The blood, therefore, remains congested in the overfilled vessels of the nose and face.

LONGEVITY OF THE SEXES.—Recent statistics on the comparative longevity of the sexes show that under 15 years there are more boys than girls, but over 75 years there are more women than men, and from the ages of 90 to 100, the proportion is about three to two in favor of women.

CRIME AND STRONG DRINK.—Lord Napier, in a recent address before the Church of England Temperance Society, said that while commanding the armies of India a return made to him, relating to 18,000 men, showed that among the total abstainers there were no crimes, but the whole body of crime was among non abstainers.

BEE STINGS.—Bee-keeper: The pain and injury from bee stings is quickly cured by onion juice. Cut an onion in two and apply one-half over the part as soon as you can after being stung.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

RUNNING.—Amador *Sentinel*, Nov. 11: The Shugart mill is now running its full twenty stamps. The appraisers of the Zeile estate have appraised the Zeile mine at \$20,000. Crushing will be commenced at the Reed mine, Irishtown, the latter part of the week. J. C. McNamara had a crushing at the Kelly mill last week, but we did not learn the amount of the clean up. A strike of proportions represented to be large and rich has been made at the Anderson mine.

RAINBOW.—*Ledger*, Nov. 14: This quartz claim is situated in John Belluomini's ranch, about a mile and a half south of Jackson. Louis Isola, a miner from Calaveras county, has been working there for the past eight or ten months, in company with another party, on shares with Belluomini. At the depth of 43 feet they have drifted a considerable distance on the foot wall, and have discovered a ledge from 6 to 10 feet wide of live looking quartz, all of which is said to prospect well, and is calculated to yield by mill process from \$7 to \$10 per ton. It carries none of that heavy black mat with iron in the Nevills, and other mines south of the Zeile, but the general appearance of the ore gives promise that the discovery may lead to the development of a substantial mine. They have out about 200 tons of rock, all of which is believed to be of good paying grade. This mine adjoins the Red Cloud, near Murphy's gulch, owned by the Moon Bros.

MISCELLANEOUS.—T. E. Flagg is making considerable improvements around the Lighthouse mine, at Butte City, lately purchased by him from W. E. Stewart. He has built a fine chute to run the ore to the mill, and has quite a body of ore, but whether of paying quality remains to be seen. He has not milled any since becoming the owner. He has brought up his family from below, evidently intending to stay with the mining business. The five-stamp mill of the St. Louis mine near Pine Grove is expected to be started to-day, Saturday. As the ore paid expenses when worked by the slow process of an arastra, it ought to pay handsomely with a mill. There is considerable ore ready for crushing. It is reported that the sulphuret works are to be put up at the San Joaquin mine, near Pine Grove, to work the sulphurets of that claim. The ore contains a large percentage of sulphurets.

Calaveras.

WHAT CHEER MINE.—Calaveras *Chronicle*, Nov. 13: Work on the What Cheer mine is steadily progressing in spite of the difficulty caused by the influx of water which the company has had of late to contend with. The machinery throughout is in fine running order, and is propelled exclusively by water power. The company have lately erected a fine five-stamp mill, also boarding and lodging houses. The mill is kept running day and night, crushing on an average of 75 carloads in 24 hours. Hoisting is done by means of a hurdy-gurdy with excellent water power. The pump, which was heretofore used to drain the shaft, has been replaced by a larger one, the old one having been found insufficient to keep the water under control. The pump is connected with an air-compressor which keeps the shaft continually supplied with fresh air. The shaft is now down 600 feet. Sinking and breasting was resumed 1st Wednesday, it having been suspended for some time past on account of the trouble with the water, but there was already sufficient gravel on the dump to keep the mill running. Sixteen men are employed in the mine, besides a number engaged in cutting timbers in the neighborhood. There is no doubt but that this mine, under the present good management, will prove a valuable property, and we expect to hear of substantial returns in the near future.

WEST POINT.—The revival of the mining industry is steadily improving. In spite of the inclemency of the weather the work will go on, and if the worst comes, it will be prosecuted between showers. The abundance of water in the streams, caused by the late rain, has supplied the ditches with a sufficient quantity of the aqueous element to start the quartz mills and reduction works in full blast, giving the proper impetus to the mining business and bullion yield of this district. The Russell Reduction Works, together with their mines, will, in all probability, be sold during the present month. The price to be paid is \$75,000. The sale of the Lone Star, Reed & Hillary and Riverside mines will be consummated within the next 10 days without a doubt. The price to be paid is \$30,000. The Fine Gold mine near this place, which was recently sold for \$25,000, cash down, is being placed in condition to be prospected and developed on a reasonable scale during the coming winter. Water power will be used to propel all machinery erected, which will be hoisting works and a 10-stamp mill. Roads have been finished and excavating completed, and a large force of mechanics are busily engaged in building and placing the machinery in position. The body of ore to be worked in this mine, as it shows at present, is 100 feet in length by three to five feet in width. Average value of ore is about \$20 per ton. The Keltz mine is steadily undergoing development. Depth of main shaft is 60 feet. The south level is six feet in length; width of ledge in face of said level is three feet; the ore body extends 96 feet in length in north level, making, as far as explored, a body of ore 50 feet in length and 2½ feet in average width. The last crushing taken out of the mine, which was extracted from the bottom levels, amounted to 28 tons and yielded 166 ounces of gold. The Soap Root mine, owned by John Henry, is looking well. The flow of water has increased so, and pumping facilities being limited, sinking has had to be suspended for the present. Powerful machinery is soon to be placed on the mine, when operations will be resumed and the shaft sunk 200 feet deeper. Eight tons of solid sulphuret ore, which is now on the dump, will be reduced at the Russell furnace. Heavy machinery is now on the way from the city to be placed on the Scorpion mine, which is in close proximity to the Soap Root. The Oro Fino mine, owned by the Cook Bros., has changed hands. The price, I believe, is \$20,000 to be paid in installments.

Inyo.

POLETA.—Inyo *Register*, Nov. 13: They are stopping from the old main tunnel in the Poleta, to connect with the new incline, something near 200 feet above. The ore yield is fair, but not so rich as that recently worked from the incline mentioned. As wagons can load almost at the mouth of the tunnel, the expense of sacking will be saved, and nearly all the ore may be worked to a small profit with little or no sorting. Mr. Story thinks they will have a hundred tons or so ready for milling by the first of January.

REPAIRING.—The Bishop Creek Ditch Company have a force of about a dozen men at work near town, cutting their canal out to its proper size and grade, as originally designed, and putting it into complete order generally. It is said to be badly filled up for a mile or two below the head gate.

Mono.

PATTERSON CON. ORE.—Bodie *Free Press*, Nov. 11: Reports conflict as to the actual status of matters in the Patterson Con. property at Sweetwater. One statement has it that the mine has been bonded to the Irwin party in the sum of \$65,000; another fact appears to be that the owners refused to sell to another party of capitalists for the same amount. However, work is going on and the late point is that the ledge has been struck in a new adit at the depth of 75 feet. This is in what is called the new or "Rich Strike," and it is not now known here whether the ledge has been crosscut or not. Where opened above the ledge is eight feet in width, composed of quartz boulders and fine ore in clay. From the samples brought in by a friend of the *Free Press* we have Mr. Soderling's certificates of a couple of assays as follows: No. 9003—Blue, \$225.10 gold; \$59.20 silver—a total per ton of \$314.30. No. 9004—Red, \$79.72 in gold and \$4.80 in silver; total, \$84.52.

FROM MAMMOTH.—Yesterday Frank Leonard and A. W. Curtis returned from a short trip to Mammoth district. Charley Radcliffe, foreman of the Lisbon mine, sends in some very handsome specimens of fine, free gold ore. The mine and mill are in steady and very successful operation. Mr. Leonard also presents the *Free Press* with some quartz from the old Mammoth mine, which shows solid gold "big as a piece of chalk."

Nevada.

ANOTHER DEERIS DAM.—*Transcript*, Nov. 11: The Liberty Hill Mining Company have erected a debris dam a short distance above the mouth of Little Bear river. Those who have seen it say it will successfully restrain the slickens. The parties who recently leased the Rising Sun mine at Willow Valley and are now working it, have an excellent prospect. The ledge has recently improved in size and quality.

SPLENDID PROSPECTS.—This week's developments at the Fleming mine, just above Suspension bridge, have been of a satisfactory enough character to satisfy the most sanguine stockholder. In the north drift of the 130-foot level 100 feet from the shaft, and directly under Deer creek, the ledge has widened to 2½ feet of solid ore, and is extremely rich in sulphurets and free gold. In the south drift, which has been run a distance of 110 feet, the ledge varies from six inches to two feet and is also of high grade. Some beautiful specimens from the north drift were to be seen yesterday at Cross & Simond's law office.

MINING NOTES.—Grass Valley *Union*, Nov. 13: Work on the Central mine, on Greenhorn creek, is being steadily prosecuted. The ledge in the tunnel is of good size and fair quality. The distance yet to be run to strike the rich chute from the old Greenhorn is about 100 feet. The new water wheel on the Horseshoe mine is working satisfactorily, and the water from the shafts and drifts will be pumped out by Monday. The company will then call for bids for sinking the shaft 100 feet deeper.

A PAYING PROPERTY.—*Transcript*, Nov. 12: Although the Delhi quartz mine on the South Yuba river above Columbia Hill has been worked but little over a year, it has paid, not merely all expenses, but \$15,000 in dividends. An 8-stamp mill and four Triumph concentrators comprise the plant. Large quantities of sulphurets have been stacked at the mine, the cost of hauling not warranting their being brought to Nevada City for reduction. If further developments are satisfactory, chlorination works will be erected on the premises. A well-seamed ledge, averaging eight feet in width, is worked through a 900-foot tunnel that starts into the hill about 100 feet above the bed of the river. Another tunnel has just been run to the ledge 200 feet below the present workings. The ore is of medium to low grade and the daily crushing is twenty-four tons. This is above the average amount of work for eight stamps, but here the stamps weigh 1,000 pounds, instead of 800-pound stamps as is customary.

Plumas.

STRIKE.—Greenville *Bulletin*, Nov. 14: A few days ago it was rumored on the street that important developments had been made in the Indian Valley mine. Investigation proves the rumor to be true. Since the resumption of work in this mine under Mr. Cornell's management, the shaft has been sunk 50 feet, making a total depth of 680 feet. About two weeks ago a drift to the east was begun. Although the ore in the bottom of the shaft was rich, that of the immense ledge reached is much richer, the gold being scattered all through the quartz, and much of it is visible without a glass. The ore is of very fine quality, as a sample in this office will show. The south wall of the ledge is smooth and well defined. The breast of the drift on the ledge is 22 feet wide, but the north wall has not been reached yet. This immense body of ore is under that which paid so well when Corbin & Manson had the mine leased. The property of the Cherokee Mining Co. is advertised for sale under foreclosure of mortgage. It should be owned by the Green Mountain Co. The lower tunnel in this mine would tap the Cherokee claims at a great depth, thus avoiding the great expense of hoisting ore, an item which has prevented the successful operation of the Cherokee in the past. If operated by the Green Mountain Co. it would without doubt pay well. John Ellis and Chas. Bressler came over from the Dutch Hill country on the North Fork of the Feather river last Saturday. In their claim below that of the Dutch Hill Co., they have reached very fine gravel. Mr. Ellis is very confident that they have broken into the ancient channel which furnished the rich deposits of gold found at points below in years gone by. They expect to return as soon as the weather will permit, and continue the development of their mine.

Sierra.

GRAVEL MINES.—Greenville *Bulletin*, Nov. 11: From Mr. J. P. Hall, who has just returned from Sierra county, we have the following: Some of the gravel mines near Gibsonville have been worked for 30 years, and are paying as well to-day as ever. From the North American to the Bootjack more or less work has been done along the lead for three miles. The latter named mine used an engine under ground to pump the water, and thereby worked down the grade or lead as long as the water could be controlled. At La Porte this same lead has been extensively worked. All who are acquainted with the mines at La Porte and Gibsonville know of their richness. The largest piece of solid gold taken out at Gibsonville, to Mr. Hall's knowledge, was obtained from underneath the place where the brewery now stands and it weighed 96½ ounces. The distance between Gibsonville and La Porte is about eight miles, along and over a high ridge. The ground has long been claimed. Shafts have been sunk at a great expense, but, finding so much water, failed to reach the bedrock. The ground has finally been bonded. Mr. John Thomas has been to Europe and, it is said, has raised money enough to purchase and develop the lead. Mr. Hall says that this is considered by mining men one of the surest and best investments in Northern California. The Lincoln, at Potosi, is working quite a force and it is said is paying \$20 a day to the man. The Belmont Consolidated, near Yoker Flat, has a small crushing arrangement, put up by Mr. Forbes, of Downieville, with which, in the last ten days' run, \$1600 was taken out. Mr. Southerland has put up a mill on the extension called the Sierra Phoenix, and it is said that he is doing well. The Young America, near the Sierra Buttes, is very rich. Shares (fourths) that sold a few months ago for \$1000 are now worth \$75,000. The ledge lately struck in Gold valley is causing quite an excitement. It was struck on each side of the valley by different parties the same day, and is said to be exceedingly rich. Gold valley lies near Gold Lake, between the Plumas Eureka and the Sierra Buttes. At Soda Bar, in a claim that had been worked and reworked, the owners struck gravel under what was supposed to be the bedrock, and are taking out an ounce and a half per day to the man.

NUGGET.—*Mt. Messenger*, Nov. 13: A nugget of gold weighing 34 ounces after it was cleaned, was sold at the bank, in this place, recently. The quartz mill of Mr. Van Slyke, at Butcher Ranch, has been shut down for the winter. The mill is about a mile from the ledge, the rock having to be hauled in wagons. So soon as snow fell this work had to be stopped. The work of laying the new track in the Extension tunnel was completed Thursday noon, and the work of taking out gravel was resumed Thursday night. Nearly 1200 feet of tunnel changed from strap rail to T rail in four days and a half, is pretty good work. The Young America Company have repaired their tramway in such a manner that it will not be likely to give way again. We understand the company has just declared a dividend of \$1000 to the interest, which, considering the expense they have been to and the short time they have been running, is very good indeed.

Shasta.

PLACER AND QUARTZ.—Shasta Co. *Democrat*, Nov. 11: A few days ago Tom Green purchased another mine, paying therefor \$1900. The Potts & Foster tollroad to Bullychoop is being extended two miles further into the mining country. Work on the Hardscrabble placer mine, near Igo, will be resumed immediately, as there is now sufficient water to start with. The Buckeye miners are putting their claims in shape for a good winter's run. Such a good fall of rain so early in the season was unexpected by all. Weil, Conroy & Murray have resumed development of their Flat creek gold quartz mine. Weil informs us that they will start their mill up next month. Jake Hudson and partner are sinking on a prospect on the other side of the river above Jake's farm, which is very promising. The ore frequently yields big assays in gold and silver. H. Croft, of Churntown, was in town yesterday, and reports that two new strikes were made in Old Digging's district on Churn creek gulch, and that the quartz is rich in free gold. Andy Fife and Andy Tilden have extracted between 70 and 80 tons of high grade ore from their claim on Salt creek, and will have it crushed soon in the Meribew & Co.'s mill at Lower Springs. Geo. McDaniels and his partners are getting very rich prospects out of their claim southwest of town. The rock is heavy with fine sulphurets, which carry most of the metals, and assays "way up." The vein is a large one, running nearly north and south. The rain affording plenty of water for the purpose, Reid & Co. started their quartz mill in full blast Monday, with the accomplished young engineer, Lou Gross, at the throttle. Sufficient water, and with plenty of good ore on the dump, a profitable run is anticipated. Development work is still being vigorously pushed ahead on the Morely mine on Cow creek, and the outlook is very encouraging, becoming brighter as the depth is attained. Mr. Morely is of the opinion that his is one of the richest small mines in the State. We hope so, and may it continually richer grow. Meribew & Co., of Lower Springs, have one of the finest quartz milling and concentrating outfits in the country, which is now running in tip-top shape, and commenced crushing the first of this week. The machinery is being driven by steam power, and with two Frue concentrators they will put through regularly ten tons of ore a day.

Siskiyou.

PICK AND PAN.—Yreka *Union*, Nov. 13: Mining operations will be commenced in a number of placer claims on the Salmon, the late storms having filled the gulch streams, and left several inches of snow on the high peaks. The Montezuma placer mine, at Callahan, is in ship shape, and will be operated as soon as sufficient water can be had. Many improvements have been made in the mine during the dry season, such as putting in new boxes at the head, repairing the flume and replacing worn blocks with new ones. A large force will be employed and the mine will be superintended by Mr. James B. Parker, who managed it with such excellent success last season. Mining on the Klamath has closed for the season, and many of the mine owners had the misfortune to have their wheels carried off by the sudden rising of the river. The Empire mine lost every wheel excepting the dip, and the miners were driven

from work just as bedrock was reached. The last three buckets of dirt washed yielded \$25. The windmills of the Phil Mott and Fort Jones were also washed out, and both companies sustained heavy losses. The Kanaka company and the three Chinese companies in the same district escaped loss this year. McConnell pulled out just in time, as he always does. The Black Bear has just cleaned up after a run of 26 days, and the result was much better than Lieutenant-Governor Daggett expected. The Bullion was brought out to Etna last Friday by Mr. O. L. Daggett. The mill has been running by steam, but the late rains will, no doubt supply water enough to run it until heavier storms come, which will reduce the cost of milling considerably. All the dumps are full of good paying rock, and a rich strike is reported to have been made in the mine during the past few days.

Trinity.

A BIG STRIKE.—Trinity *Journal*, Nov. 14: Wm. S. Lowden informs us that the Brown Bear Co. at Deadwood, struck their ledge in the lower tunnel last week. When he left they had run four feet into the lode without crossing it, and it showed free gold all the way. This confirms the depth, permanence and richness of Deadwood veins, which has always been claimed, but never before proved. We hope for more particulars. Trinity river raised several feet during the storm, but soon went down, although it will not be as low again as during the summer. It was about as low this season as ever before known by the whites. The North Star Co. on East Fork, have had made a quartz wagon to haul the ore to the mill with.

Tuolumne.

ACTIVITY IN QUARTZ MINES.—Tuolumne *Independent*, Nov. 14: The Belcher Consolidated, or Onesti mine at Deer Flat, has been sold to parties in San Francisco who intend soon to commence active operations. This mine was worked a long time ago and yielded a good deal of gold, but since the mill was burned there has been nothing done on the property, owing to a disagreement amongst the stockholders. The mine has a very good reputation here, and competent experts say the ore will pay about \$16 per ton, and the vein is a good-sized one. Some parties are negotiating for the claim of David and William James, on the Tuolumne river near the mouth of Humburg creek. The mine continues to improve and the ore shows lots of coarse gold, and some of it is mortar rock. The Blaine mine, at the mouth of Indian creek, has been sold and active operations were commenced on the property this week. The mine was formerly known as the Garner mine. Rumor had it this week that the Cook property at Courtville and the Golden Rock Co.'s water ditch were sold to a French company, but the report lacked confirmation. It is now reported that other parties are negotiating for the ditch, with a view of putting it in good order and selling water, and perhaps working some of the gravel range. The owners of the Wide West mine are at work on their mill, which will soon be ready to run. It is among the possible ties that there will be a mill on the celebrated Mississippi mine, in Big Oak Flat, this season. The Mississippi produces some very handsome "specimen rock," and we have seen some slate from this mine showing lots of coarse gold.

SOULSBYVILLE.—Men were sent up on the Soulsby branch ditch this week to clean it out and repair the flumes. It is said that the main ditch will be repaired this week and ready to have water turned in. This will give employment to men who are now idle at this place—when water comes. Having free water in the creek, the pump at the Black Oak mine was started last week. As soon as water is obtained from the main ditch a full crew of men will be put to work sinking the shaft, as they have not sufficient free water to keep the pump and hoisting works running at this mine. The Dead Horse mine was closed down last week. This has thrown several men out of work. It will, no doubt, go on again in a short time, as it is reported that it is a good mine.

BUCHANAN.—The Buchanan Mining Co. are making preparations to construct a wagon road to their mine, which is situated about seven miles south-east of Summerville. The Dead Horse mine shut down for a short time on Saturday last, in consequence of which our little town has assumed rather a gloomy appearance. Mr. Burnell is having a quantity of rock hauled from the Seminole mine to Easton's mill, at which place he intends to have it crushed in the near future. Clark & Brown will start the Louisiana mill in a short time.

MINE AND MILL.—Union *Democrat*, Nov. 14: Operations will be resumed in the Crystalline mine and mill next week. During the season of enforced idleness the mill has been put in complete repair. All the 25 stamps of the Heslep mill will be running and the mine started up with a full working force next week. The rains increased the water sufficiently to start everything up. On account of the rain, which delayed the transport of some needed supplies, there has been some delay in getting the Buchanan mill ready for operation. The mill is already completed and as soon as some necessary belting for the Frue concentrators arrives crushing will be commenced.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Enterprise, Nov. 14: The north lateral drift on the 3100 level is being steadily advanced, and is now 89 feet beyond the deep wine station. The whole face of the drift is in good ore, which is a very promising circumstance for that particular locality, as it corresponds with what is developed on the 3000 level at about the same distance north, both being within 100 feet of the Savage south line. Crosscut No. 2, on the 3100 level, 90 feet north of the Chollar line, has been turned more to the north, following a promising section of the vein. A large amount of strongly-mineralized quartz was passed through by this crosscut, which promises to concentrate into something good at some point.

CHOLLAR.—On the 3100 level the main lateral drift south has been pushed along very energetically during the week, about 75 feet being its advancement, making a total length of 345 feet. It is being run in wall rock on the west or "hanging" side of the vein. The material is dry and easy working, and Superintendent Hamilton says he is going to push it for all it is worth toward the Potosi line, not crosscutting at present, or until it shall be considered advisable. Everything is running splendidly at the Combination shaft, and as soon as the present 3100 level of the

middle mines shall be considered sufficiently prospecting, sinking for the 3200 level will be in order, and not before.

CROWN POINT.—Over 300 tons per day are now being shipped from this and the Belcher mine, principally from the old upper levels; quite a respectable contribution comes from the 1700 level, where some pretty good ore is being breasted out. This corresponds to the good streak of ore in Belcher on the same level, and forms a connection with the main drift being carried through Kentucky into Yellow Jacket. The 1700 level of these Gold Hill mines promises to cut quite a figure in future mining operations in that section of the Comstock.

YELLOW JACKET.—The usual amount of ore to supply the Brunswick mill, about 170 tons daily, is extracted and shipped, coming from the old stopes and breasts above the 1300 level, all being shipped without assorting, thus dispensing with the services of many men. But this is merely being tried by way of experiment. The mill is being run altogether by water power now, the Carson river having raised sufficiently to allow of it. Good progress is being made on the 1700 level drift, from Crown Point through Kentucky to prospect that level of this mine.

CON. CALIFORNIA AND VIRGINIA.—About 120 tons per day continues to be the yield from the 1750 level, assaying \$18 per ton. The northwest drift on the 1650 level is also being extended in order to get at some ore in that direction. From the Jones lease section, above the 1500 level, nearly 100 tons per day are being shipped to the Eureka mill, assaying about \$13 per ton.

KENTUCKY.—The old upper workings contribute their daily quota, as usual, toward the running of the Rock Point mill, on the Carson river, and also supplies the Longglass mill, of 10 stamps, in Gold Canyon, which is the property of Superintendent Stevenson.

ALTA.—On the 700 level the drift west has at last cut through into an ore body formation for which it has been running, but not far enough advanced to estimate or fairly understand the value of the low-grade bonanza met with.

OPHIR.—The lateral drift south on the 400 level is now in about 190 feet, following a very promising quartz formation, with occasional streaks and bunches of ore. No upraising is commenced yet above the main west drift.

SIERRA NEVADA.—On the 520 level the lateral drift north from the west crosscut is running in very favorable vein material, decomposed quartz, soft porphyry and clay, with some little water.

BEST & BELCHER.—The lateral drift south on the 1000 level continues following the strongly-mineralized quartz formation it was started to explore, but shows no particular improvement as yet.

MEXICAN.—On the 500 level the middle crosscut shows no particular change from last week. Material, decomposed quartz, vein porphyry and heavy clay.

UNION CONSOLIDATED.—The crosscut east on the 500 level, 100 feet south on the Sierra Nevada line, is progressing well in promising vein material.

GOULD & CURRY.—On the 100 level the crosscut west is now in about 70 feet. Material, vein porphyry, decomposed quartz and clay.

MONTE CRISTO.—Getting out ore enough to keep the mill running. Will resume sinking the new shaft shortly.

Dun Glen District.

NEW PLACER MINES.—*Silver State*, Nov. 13: There is some excitement at Dun Glen over the discovery of gold bearing gravel in Barber's canyon, on the western slope of the range. Quite a number of claims have been located, and Vance Nelson, who arrived from Dun Glen yesterday, says a shaft has been sunk 35 feet deep in the canyon without encountering bedrock, and five feet of the gravel in the shaft is said to be rich in gold. Two gold bearing quartz leads were discovered in the canyon years ago, but they were not prospected to any great extent.

Eureka District.

IMPROVEMENTS.—*Eureka Sentinel*, Nov. 11: Improvements about the Eureka Con.'s smelting plant appear to be the order of the day. The new water-jacket furnace in course of erection will be completed in two or three weeks, when the plant will be one of the most perfect in the West. Last May, when the furnace now in operation was completed and work resumed, Superintendent Robbins thought he had connected with the works all necessary improvements for the ready handling of ores, but from time to time he saw imperfections which he has done away with. Considerable custom ore is being hauled to the works from the mines of the district this week.

Hawthorne District.

THE LAPANTA MINE.—*Virginia Enterprise*, Nov. 15: A telegram from Hawthorne last evening says: Hawthorne District is looking most favorably. The main incline of the Lapanta mine is down sixty feet, showing a vein two feet in width, giving an average assay of \$135 per ton. Two hundred feet east, shaft No. 6 is down thirty feet; ledge looking well and averaging \$100 per ton. William M. Lent passed here en route for Bodie, this evening, in company with Captain John Kelly. Miners from Bodie report the 700 level of the Mono mine to be a failure.

Lone Mountain District.

SPLENDID PROSPECT.—*Elko Free Press*, Nov. 14: During the past two weeks there has been considerable stir over the discovery of a very rich and promising ledge in the King mine at Lone Mountain district, about 23 miles northwest of Elko. The claim in question is owned by Mr. S. G. Weston of this place, who has been mining in that district for the past five years. There are two shafts on the claim, one being 75 feet in depth, the other 65 feet. At a depth of 50 feet a crosscut was run, and an incline started down on the ledge, which pitches to the west. This incline is now down about 20 feet. When first struck the ledge showed about 10 feet of pay ore, which has now increased in the incline to 14 feet. The ledge is well defined, having a porphyry foot-wall backed by granite, and a hanging wall of lime and ironstone quartz. The ore is free milling, and can be mined and milled for less than \$6 on the ground. It assays in gold and silver from \$25 to \$300 per ton. There are now on the dump upwards of 300 tons of pay ore, worth about \$5000. The ore in sight in the mine is estimated at \$50,000. There is connected with the property a water-right sufficient to supply power to run 30 or 40 stamps. There is a

good road to within one-half a mile of the mine, which is situated on the west slope of Lone Mountain. Considerable surprise was manifested by a party of gentlemen, who visited the claim last week, over the fact that Lone Mountain contained such a fine property, and that so much work had been done. Aside from the King, there are several splendid copper claims, which will undoubtedly be heard from in the near future. It is quite likely that the King mine will be extensively worked next season and made to show its worth.

Lewis District.

GOLD.—*Central Newsman*, Nov. 11: J. E. Satter and R. A. Hazlett have struck a vein of ore in the Alleghany mine, at Lewis, that shows virgin gold all through the ledge. Both men are greatly elated over the find, and think that their fortunes are made. John Kae, J. N. Finley, J. H. Green and John Rhodes have struck some very rich ore in the Sunbeam mine, situated on Morning Star Mountain. The Morgan mine still continues to produce an abundance of good ore that turns out gold bullion to the satisfaction of its owner. Other mines in the district are looking well, and the prospects of the camp are brightening up. Everyone is encouraged by the new developments, and the old miners and prospectors go to work with renewed energy.

Pahrnatag District.

BULLION.—*Pioche Record*, Nov. 11: Eugene Howell shipped up another bar from Pahrnatag, value \$1241.41, 964 fine; result from 15 tons of ore, showing extraction of \$82 for every ton worked. He has thus made a thorough test on 34½ tons of ore from the new find, having made two shipments, in total \$2542, taking out in wet crushing in this heretofore considered base ore from 80 to 87 per cent of the assay value, or \$72.10 for every ton. This test fully demonstrates with systematical working and economical management that the mines in Pahrnatag still possess merit, and when handled on a proper basis can be made to pay.

Reese River District.

THE MANHATTAN MINES.—*Virginia Enterprise*, Nov. 12: The Manhattan mill, in Austin, has started up again, and is rolling out the silver bullion after its good old style, disposing of the rich ore which has been accumulating since July, when the mill took a rest. The richest and best of this ore is that taken out by tributaries. It is in small, separate lots of a few tons or so, yielding all the way from \$300 to \$5,000 per ton, and the boys have been waiting very anxiously for their little "crushings." The heavy lawsuit against the Manhattan Company by outside parties has operated as a sort of deadlock or embargo, but this being arranged, the mill is now turning loose these desirable resources. The mill was started up to crush up the ore on hand, and is doing excellent work. At the Lander shaft the several tribute stopes on the 700 and 740 levels continue to produce ore in limited quantities. Stopping is also being carried on in the 650 and 800 levels. The Paxton incline section continues to produce the usual amount of ore from the tribute stopes in 950, 1350, 1440 and 1500 levels. The 1440 west drift is being extended and carries very good ore in the face. At the Union shaft the south crosscut shows no change. The east drift on Union ledge is being continued, showing spots of good ore with a large ledge. Several parties of tributaries are taking out some ore on the several ledges already cut.

Rebel Creek District.

ORE FROM THE OHIO.—*Silver State*, Nov. 13: Last evening E. O. Connor's team arrived here with about 15,000 pounds of rich ore from the Ohio Company's mine at Rebel Creek.

San Bernardino.

ORO GRANDE.—*Calico Print*, Nov. 15: We were informed that the Oro Grande Mining Company's mill at Oro Grande has been leased to Denver capitalists for six months, with the privilege of purchasing same. The Denver capitalists are represented by Mr. Canfield, and should they find suitable mining property at Soda Lake, then a smelter will be erected at Oro Grande, where there is good water power and plenty of wood. The Calico Mill and Mining Co.'s mill at Daggett has been idle during the past week. Litigation is partly the cause of it, but it is expected soon that the mill will be running regularly.

CALICO.—The Jessie Tay and Rose Bud claims, owned by Anderson and Ackerman, have been bonded to Porter and Waterman, who are at the present time taking out some good ore. The Dora Belle mine is showing up some good mineral, a continuous vein 6 inches wide of 100 oz. ore is being worked on the claim. A streak of high grade ore has been struck on the Alhambra mine. This mine is owned by the Golconda and Alhambra Mining Co., Mr. Rodgers representing the company as superintendent. Work is being pushed ahead on the Young Waterman claim. It is the intention of the owners of this mine to develop it systematically, and not gouge out every little pocket of ore they happen to strike, although some very high grade ore has already been taken out of the shaft which is being sunk. The Sue mine is still looking very well, and is holding its own as regards shipments. The Humbug mine will shortly be worked again.

Willow Creek District.

PROGRESS.—*Co. Eureka Sentinel*, Nov. 14: The mining industry has made great progress in this district during the summer. Steady industry has taken the place of false representations, and solid developments have succeeded vain attempts at booming, which characterized the camp a few years ago. The Wild Deer claim, which, one year ago, was a mere prospect, has developed into a mine of no mean proportions. About 1200 feet of tunnels, drifts and inclines have been run upon the ledge. Several hundred tons of assorted ore have been mined and worked successfully at the mill—all taken from a small portion of the ledge above tunnel No. 1. The work done upon the ledge up to the present time shows a continuous ore body 250 feet long, 100 feet wide, and 3½ feet in thickness. We find occasionally barren streaks in it, but to make up for such spots, we have bunches of horn and native silver in other parts, which assay from \$300 to \$1000 in silver and gold, the latter metal holding over one-fourth the value all through the mine. Every foot of development shows richer and better prospects. The ledge below the 100 level has never, pinched or broken, and the mine can be worked for 1000 feet deep by tunnels run directly upon the ledge, which fact alone saves an immense amount of ex-

pense in working. The ore is growing richer in gold as depth is attained, the base bullion shipped to San Francisco running over two-fifths in gold in value. Bill Long still has charge of the mill and has made a record in handling the ores of the district, which is a credit to himself and the town he hails from. A new toll road is now nearly completed up Flat Creek a distance of four miles to a point just below the mine. Quite a large force of men and mules have been engaged on it for the past two months. It will be a great advantage to the Wild Deer as well as other claims on the creek, and is a pretty good evidence of the prosperity of the camp. Two hundred tons of the richest ore ever taken from the Wild Deer now await the completion of the road in order to be shipped to the mill by team, which will be a great improvement on the old way of packing by mule trains. The Ohio mine has been developing steadily under the management of Mr. William Caruthers. They have shipped enough ore to Salt Lake since buying the mine last November to pay all the expenses of development. A new tunnel 350 feet long has been run, which taps the mine at a much greater depth than heretofore. The ore is very high grade, and the mine is owned by a very strong company that talks of erecting a mill on Willow Creek next spring. During the summer the irrepressible prospector has not been idle. Several new finds have come under my notice, some of which, on the same ledge as the Wild Deer, promise finely for the amount of work done. All the camp needs is more muscle and less jawbone. We want men who practice less at the bar and more on the head of a drill.

ARIZONA.

CLIFTON CLARION.—Nov. 11: A ride of a half hour last Saturday morning on the Narrow Gauge Railroad brought a reporter of the *Clarion* to the Metcalf mine. Everything bore the look of prosperity. A strike of gray ore or sulphide of copper was struck recently, carrying about 35 per cent copper. The other parts of the mine are looking in splendid shape. A fine body of ore was struck in the 80 foot level of one of the Metcalf group a short time ago. Messrs. Dineen, Guthrie & McDermott have struck a new body of copper ore in their Lafayette mine, which adjoins the famous Alaska. The vein is 8 feet wide. Mr. John Hill has leased the ore dumps between the Metcalf and Queen mines and informs me that he is making it pay very well, assorting the dumps for shipment to the smelter. The news from the King mine is encouraging, too. In sinking another shaft from the 100 foot level, the ore is looking very much better than in the former shaft, and the prospects for this becoming a fine mine in the future are good. The White Hawk is looking better than ever, and Louis Jentzen still continues to ship very rich copper glance. The Detroit is looking as well as ever with ore still of a good quality. The drift run in bottom level to tap winze, was completed a few days ago, opening up a considerable body of fine ore. Mr. Barry, foreman for Captain Cutler, with three men, is kept busily employed taking out lime rock at the Longfellow to be used as flux by the Arizona Copper Company. The Longfellow mine is looking well and producing chiefly what is known as red ore. The incline shaft has been working now for over two months and the output consists principally of this kind of ore.

COLORADO.

SUMMIT COUNTY.—*Breckenridge Journal*, Nov. 11: The mills at Lincoln put in a full week at good pay. The placer workers have all closed down for the season. The Gold Dust lode will send 20 tons of ore to the Russell-Nashold mill next week. During the last week we are assured the Eureka has treated some very valuable ore said to run into the hundreds of dollars per ton. From now until next spring our gold reports will be confined to mines so far developed and equipped as to be able to work without inconvenience amid our Alpine snows and Arctic winters. The Brooks-Snyder mill is running steadily, the rail has been laid into the tunnel and an iron car now does the work of the wheelbarrow with twice the effect from half the labor.

CUSTER COUNTY.—*Rosita Journal*, Nov. 11: Judge Hoyt received about \$700 this week royalty money for Maverick ore. The ore body in the Maverick is increasing in richness and size and making a fine showing. James Kurtz has taken a lease on the Silver Cloud shaft of the Maverick mine and is driving a crosscut to the south at a depth of 60 feet. The shaft on the Dinero is now 160 feet deep and shows several small feeders from the vein. Drifting will be commenced at a depth of 175 feet, and it is confidently expected that the ore body will be tapped soon. Work was commenced on the Lizzie Mac lode Monday. The property is developed by a 90-foot shaft and a short drift at the bottom of the shaft. The Aspen, an extension of the Maverick, has been leased for six months from the time of striking pay ore, to James Kurtz and others. The shaft will be sunk to a depth of 60 feet and then a crosscut run to the south. James Hudson, a Pueblo machinist, came up last week to set up a new patent hand hoister for C. G. Mathews. The machine is an invention of Mr. Hudson's and is said to be a great improvement on the windlass. It is being used on the Lizzie Mac lode on Columbia Park. The Security Company purchased eight claims at Silver Cliff recently with the Silver Cliff mill which they are preparing to commence active operations on at an early day.

IDAHO.

THE NEW DIGGINGS.—*Coeur D'Alene Record*, Nov. 15: Last week Mike Rochford came to town directly from the St. Regis, and from him and others the reporter gathered the following particulars regarding the new placer field. On Deer creek, which empties into the St. Regis a Borgia river about four miles below Crow's Nest, 22 locations have been made and three water rights taken. A mining district, quartz and placer, has been established which embraces all of the country drained by the St. Regis, and is to be called the St. Regis. No bedrock has ever been found on Deer creek, although one shaft has been sunk to a depth of 25 feet, but from the surface to the lowest depth found the gravel prospects about the same. Mr. Rochford and partners whip-sawed lumber and made six sluice boxes. These had been run but a little while before he came away, but the little they shoveled in, by weight and meas-

urement, gave 15 cents in gold to the cubic yard of gravel. The creek has a good fall, and 600 inches of water and its bottom will average 600 feet in width for its entire length. Comment is unnecessary, but we must say that at these rates it will prove a paradise for hydraulic miners.

MONTANA.

STAR.—*Butte Miner*, Nov. 11: During the week just closed the only development worthy of special mention is the cutting of the vein in the south drift on the 500-foot level of the Rising Star, one of the Alice Company's properties. The drift in question has been run in 200 feet from the shaft, and on Thursday tapped the vein, which has been cut into five feet, with no indication of striking the opposite wall, and the ore is of a splendid grade. With such quartz in the crosscut and a continuation of the same grade of ore in the 800 drifts of the Alice proper, it would certainly hold that the deeper the mines go there is no diminution either in the quality or quantity of the products of the veins.

THE MOULTON.—During the week the mill was shut down two days for necessary repairs and putting in new driers, but is again in good trim and running to its full capacity. The stopes are producing as usual, both as to quality and quantity, and all the machinery is in first-class working order.

THE ALICE.—Everything about both the mine and mills of the company is running smoothly. During the week one shipment of 16 bars of bullion has been made and there are 20 bars more in the office, which will be shipped to-day. The vein in the 800-foot level is showing fully as well as at any time since it was but.

THE RISING STAR.—Work is being pushed with vigor, particularly the 500-foot level, in which the ledge has been tapped at a point 200 feet south of the shaft. The crosscut has not yet reached the south wall of the vein, but is now showing five feet of good ore. The body of ore thus opened is the best yet exposed in the mine, and from present indications is very extensive in quantity as well as of high-grade.

OREGON.

MINING SEASON.—*Jacksonville Times*, Nov. 13: A good mining season is predicted and hoped for. James Burns has returned from Portland and will resume mining operations on Applegate. The Wagner creek placer mines are in readiness and a good report is expected from them. Much more rain fell in Josephine county than in this and many of the miners there are at work. Bybee & Hall have done some piping on their mines on Canyon creek, Josephine county, and with a favorable season will take out considerable dust. J. N. Casteel was down from Big Applegate this week and reports his company and miners in that section generally as ready for an extended run. We are informed that the California capitalists who intend to run a ditch between Sucker creek and Illinois river, a distance of about 12 miles, have arrived at Kerbyville. They propose inaugurating a big mining enterprise and intend buying the claims of A. Brown and others. The Sterling Mining Company's huge, new reservoir is completed and being used with success. There is considerable water in the ditch and piping is going on, though more rain and snow is necessary to set everything going at full speed. Captain Ankeny is acting as superintendent, Frank Ennis still being unable to resume his duties. Piping was commenced last week at several of the mining claims in this country, but, as the weather has turned off pleasant, not much is being done in most cases. The same may be said of other placers that are worked in the old-fashioned way. It will not take a great deal more rain to set the miners busily at work; and all of them are anxiously awaiting it.

UTAH.

REVIEW.—*Salt Lake Tribune*, Nov. 13: The receipts in this city for the week ending Nov. 11, inclusive, were: Bullion, \$134,314.65; ore, \$27,647.80; a total of \$161,962.45. For the previous week the receipts were \$92,266.46 in the aggregate, of which \$77,441.46 was bullion and \$14,825 was ore. The Ontario product for the week was \$50,580 in bullion, bringing the total for the year up to \$1,410,019.21. The Stormont sent up on the 6th two bars of silver valued at \$3610. The product of the Hanauer smelter for the week was eleven cars of bullion, \$29,600; the Germania, four cars, \$9873.70. Ore receipts were \$7150 in the Lead mine, \$6850 from the Crescent, \$3100 from the Sampson, \$374 from the Lion, Utah; \$5670 from the Queen of the Hills, and \$3277.60 from the Bannock, Idaho; \$1150 miscellaneous, and \$136.20 from the Flagstaff, Nevada.

PARK.—The Ontario Company paid off on Wednesday and Thursday. A force of carpenters have been put to work making improvements on the Empire hoisting works, ostensibly for the purpose of protecting them against the heavy snows of this winter, and we understand that in early spring this company will resume work on the mine.

THE SANDSTONES.—*Salt Lake Tribune*, Nov. 14: Rich ore was struck in a new prospecting shaft on the Butte mine last week. A shipment of sulphides was made from the Leaching Works to Salt Lake last week. The Little Chief, Gisborn and Golden Gate mines have a big showing of low-grade ore that will pay a good profit to the reducer. The Leaching Company has a force of mechanics putting up the plant and sometime next week the ten leaching tanks and four precipitating pans will be in place. Wells, Fargo & Co. carried 31,704 ounces of refined silver out of camp last month. Of this amount the Stormont produced 20,920 ounces, and the Christy, in 15 days' run, 10,784.17 ounces. The old Bonanza, abandoned, then relocated last January, has enough ore exposed now to prove that it is a big mine; it has yielded within the last few weeks more than 100 tons of rich ore to the chloriders. There are many claims in town and on East and Central Reefs, that were abandoned until recently, when most of them were taken in hand by chloriders, many of whom were poor men; all are yielding good wages and several are proving bonanzas. The old Leeds mine, which has produced hundreds of thousands of dollars and was so badly gouged out by a grab-all-in-sight management such as the Horn Silver has been afflicted with for years, is still a profitable property.

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned this title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding homastic and pretensions claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

The Rains.

The rains have fallen abundantly all over this coast this week, and gladdened the farmer's hearts. Up to 3 P. M., to-day (Wednesday), this present storm has given us in the city 4.23 inches, or 7.84 inches for the month of November to date. The season's rainfall so far is 8.73. On Tuesday morning this waters fall heavily. Between five and six A. M. we had .87—a good fall for one hour; and in the four hours between 4 A. M. and 8 A. M., the fall was 1.14. Some persons supposed that the rainfall then was phenomenal, and that we had never before had so much at one time. Mr. Thomas Tennent, who has kept rainfall records since 1849, has kept track of heavy falls of water and gives us some figures which show heaviest rainfalls in 24 hours in this city, whenever it exceeded three inches. This record is as follows:

Date.	Inches in 24 hours.
December 17, 1852.....	3.00
April 16, 1853.....	3.45
January 9, 1852.....	3.50
November 24, 1854.....	3.93
December 19, 1856.....	4.23
December 20, 1856.....	4.23
December 18, 1871.....	3.22
December 19, 1881.....	3.49
December 23, 1871.....	3.48
November 23, 1874.....	3.78
March 6, 1879.....	3.47
December 29, 1881.....	3.74

This month we have had several very rainy days. The heaviest this month in 24 hours according to this record was 1.72, which was on Nov. 6th.

The rainfall in this city so far this month beats this record for any previous year since 1850, this measurement for November in that year being 8.66 inches. The total rainfall this month will bring the record closely to that of November, 1850, if not exceed it. In the latter event, November, 1885, will go on record as the best month in rain statistics.

Mining Share Market.

There is very little change to note in the mining share market. On the Comstock the principal locality and centralization of interest so far as the deep levels are concerned lies in the middle mines, Hale and Norcross, Savage and Chollar. There is very little to say even of this important point or section of the Comstock. The managing powers are simply doing the best they can to develop a paying mine. Thus far in Hale and Norcross, the chief point at issue, the much-desired bonanza has not been uncovered, yet the prospects for a real, first-class one still hold good. Veins of rich ore are developed on the 3000 and 3100 levels, tending principally toward the Savage mine, and the explorations are conducted in that direction as well as westward. The face of the main north lateral drift on the 3100 level is all in good ore, also the face of crosscut No. 3 and farther south.

The north end of the Comstock is looking up, in Ophir, Consolidated Virginia and elsewhere, and the chances are that the tracings of the grand old lode for miles beyond the Utah will be practically followed up the next season as they never have before.

The recent stormy weather had the effect to raise the Carson river considerably, so that the mills have been able to run nearly all of their stamps. More water, however, is needed, induced by more storms of either snow or rain.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco.

AUTOMATIC DINING TABLE CO.—Nov. 16th. Manufacturing and selling an electric dining table, invented by Charles A. Grellwitzer. Capital stock, \$100,000, in 100,000 shares. Directors, Chas. A. Grellwitzer, Joseph T. Pohlman, Abrie O. Colton, William Wankowski, William T. Attinger, Daniel Reynolds and F. Schafer.

ELDRIDGE MINING CO.—Nov. 17th. Location, California. Capital stock, \$1,500,000. Directors, N. Eldridge, H. O. Stearns, J. L. Buckman, George N. Gray, H. D. Weld, Walter Rosie and G. N. Whittaker.

CALIFORNIA QUARTZ MINING CO.—Nov. 14th. Capital stock, \$500,000, in 20,000 shares. Directors, A. B. Paul, E. Hestres, A. B. Paul, Jr., J. Henricks and John Mullen.

Bullion Shipments.

Odessa Mill, Nov. 15; Barber's Mill, 15, \$500; Calico Mill, 15, \$3463; Lapanta, 15, \$15,000; Hanauer, 10, \$5300; Ontario, 10, \$30,580; Vienna, 10, \$2564; Hanauer, 11, \$7950; Lead, 11, \$2850; Queen of the Hills, 11, \$2810; Alice, 12, \$22,545; Hanauer, 12, \$2490; Crescent, 12, \$2510; Queen of the Hills, 12, \$1100; Nevada ore, 12, \$400; Germania, 13, \$4794; Hanauer, 13, \$5100; Queen of the Hills, 13, \$1200; Hanauer, 14, \$2490; Germania, 14, \$4690; Germania, 15, \$4861; Hanauer, 15, \$7800; Stormont, 15, \$2960; Lead, 15, \$2130; Mayflower, 15, \$1700. The banks of Salt Lake city report the receipt for the week ending November 19th, inclusive, of \$134,314.65 in bullion and \$27,647.80 in ore, a total of \$161,962.45.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING NOVEMBER 10, 1885.

- 330,014.—WINDMILL.—Edward Gilman, S. F.
 330,020.—SAW-MILL SET WORKS.—D. L. Harbach, S. F.
 330,111.—BLACKING BRUSH AND SCRAPER.—C. E. Hatch, Vallejo, Cal.
 330,025.—SPRING VEHICLE.—M. P. Henderson, Stockton, Cal.
 330,156.—BOILER FURNACE.—John Mailer, S. F.
 330,151.—MOTOR FOR PROPELLING CARS, ETC.—L. C. Pressley, S. F.
 329,957.—INSECT DESTROYING DEVICE.—F. A. Ruhl, Stockton, Cal.
 329,958.—CORE FORMING APPARATUS.—Richard Savage, S. F.
 329,959.—CORE MAKING MACHINE.—Richard Savage, S. F.
 330,162.—VEST PATTERN.—Shively & Clark, Toana, Nev.
 330,071.—ELECTRICAL CONDUCTOR.—A. C. Tichenor, S. F.
 330,072.—ALLOY.—A. C. Tichenor, S. F.
 330,078.—SIPHON PUMP.—F. Whitman, S. F.
 330,080.—PIANO ACTION.—Fredk Zech, S. F.
 NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

DELINQUENT NOTICE.

The Orleans Mining Company—Location of principal place of business, San Francisco, California. Location of works, Grass Valley township, Nevada

PACIFIC IRON WORKS

1850. 1885.
RANKIN, BRAYTON & CO.,
MINING MACHINERY.

San Francisco: 127 First Street.
Chicago: 100 N. Clinton.
New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

WATER JACKET SMELTING FURNACES

THE DUNCAN CONCENTRATOR

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

HOISTING WORKS

Iron and Machine Works.

Golden State & Miners Iron Works.

Manufacture Iron Castings and Machinery of all Kinds at Greatly Reduced Rates.

ORE CRUSHER.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against this Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street.

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED.

PRICE, FIVE HUNDRED AND FIFTY DOLLARS
(\$550.00), F. O. B.

THE "TRIUMPH" TRIUMPHANT!

In a competitive trial recently had between two of the "Triumph" Ore Concentrators and this same number of "Frue" Vanning Machines, at the mill of the celebrated gold producing Original Empire Mill and Mining Company, in Grass Valley, Nevada County, Cal., the "Triumphs" produced thirteen and fifteen one-hundredths (13.15) per cent more concentrations than did the "Frue" Vanners, during a run of twenty-four consecutive days, or a net gold coin result of \$199.15, or \$3.30 per day, in favor of the two "Triumph" Concentrators.

These returns do not include the value of the amalgam saved by the "Triumphs" during the test; which will add to the net gain. The form of construction of the feed bowl is such that considerable amalgam is necessarily saved, which is lost on the "Frue" Vanners.

This trial was conducted under the personal supervision of the Manager and Superintendent of that Company, in a strictly fair and impartial manner, and with the sole view of determining, in the interest of that Company, the merits and demerits of the respective machines by a thoroughly practical test. A relation of the course of procedure, a concise analysis of assays, and a tabulated statement of the net bullion results, with accurate deductions therefrom, will soon be published in Circular form.

The superiority of the present construction of the "Triumph" over the form originally introduced, together with the demonstrated results of the above, and other trials had with the "Frue" Vanners, induces us to and we hereby accept the Challenge of \$1,000, flouted by the Agents of the "Frue Vanning Machine Company," and hold ourselves in readiness to enter into a second competitive trial for that sum, at such place and upon such terms and conditions as may hereafter be mutually arranged.

We guarantee purchasers against all costs, expenses or charges incurred by reason of any infringements of any existing patents.

"Put up or shut up," and "Let the Best Machine win!"

Dewey & Co.'s Scientific Press Patent Agency (ESTABLISHED 1860.)

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enabled us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not few. Circulars of advice sent free on receipt of postags. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

Working Low Beds of Gravel.

We have had our attention directed to an article which appeared in the *Rocky Mountain News*, published in Denver, Colorado, under date of Nov. 11th, relating to the successful operation of a hydraulic mining plant, which has recently been placed in position on Clear creek, near Golden, distant about 13 miles by rail from Denver.

This plant was purchased by Messrs. J. B. Chaffee and George W. Cummings, of Colorado, from the Joshua Hendy Machine Works, of Nos. 39 to 51 Fremont street, this city, through Robert J. Cory, agent at Denver, and comprises two hydraulic giants, one 16-inch hydraulic gravel elevator and one water-lifter, the latter being an auxiliary for pumping purposes to the elevator. The general plan of position and method of operation are shown in the cut herein presented in a somewhat crude manner.

As will be observed by an examination of this sketch, the elevator consists of the lower or entrance sections of heavy, well-ribbed iron pipe, cast from the best iron. These sections are set down say, five or six feet below the surface of the bedrock, the necessary excavation having previously been made for its reception. A hydraulic nozzle of proper size is then inserted into the entrance section, fixed in position, and connected by a distributing pipe line with the main supply pipe, ditch or reservoir. From these entrance sections of the elevator a wrought-iron pipe extends upwards, at an angle of 45°, to such elevation as it is intended to raise the water, earth, sand and gravel, etc., where it is connected with an upper curved portion of well-ribbed, cast-iron pipe (flanged together in sections), which discharges into an outer flume or line of sluice boxes constructed in the manner usual in ordinary hydraulic mining.

In addition to the plant, as above described, purchased by Messrs. J. B. Chaffee and G. W. Cummings, their works embrace about 2100 feet of 18-inch hydraulic pipe forming the main supply pipe line, with necessary air-valves, water-gates and distributing pipe lines to the several appliances.

The appliances forming this plant are simple in their construction, yet strong and durable, and the principles involved are based upon the hydraulic proposition that a volume of water acting under a head or pressure has an almost inconceivable impinging power or force, and experiments have demonstrated that it is as easy to wash earth, sand, gravel or other material up an ascending plane as to carry the water itself,

for it requires as much power to raise a pound of water as it does a pound of the heaviest substance. The greater the pressure, the greater the impact force, and consequently the higher the elevation to which material can be raised, the one being proportionate to the other.

Having given this rationale of the principles involved in the construction and the method of operation of hydraulic gravel elevators, we deem it of interest to our mining friends to present some of the facts of the practical operation of the plant referred to.

The volume of water at command is unlimited, and, so far as the work has been con-

ducted, about 1000 miner's inches were used when the hydraulic giants and elevator were in full play. The vertical head or pressure of this volume of water is 190 feet from point of delivery at supplying ditch to the point of operation of the elevator on the bedrock, and Mr. George W. Cummings writes to the "Joshua Hendy Machine Works," on the 12th inst., following the article in the *Rocky Mountain News*, thus: "The elevator shaft (in sinking), before the water-lifter arrived, required a windlass at each end, a large pump in the center, all running night and day, with a force of 16 men, to raise the water and sink the shaft. The water-lifter drains the shaft in eight minutes, using the smallest (three-inch) ring in the nozzle. The gravel elevator is a perfect success. I am raising gravel 25 feet with a head of 190 feet, and I will guarantee it to raise 35 feet when I am ready to lower the receiving end."

The velocity of the water and gravel through the elevator is almost inconceivable, and a calculation made of the mass of earth, gravel and sand raised, gives as a result the vast quantity of 2000 cubic yards per day of 10 hours. The process of washing, which is almost automatic, requiring only the assistance of pipe-men

Should this experiment, although it cannot even now be called such, prove successful, it will be followed by others of a like character in that and other districts of Colorado, and the result will be a large addition to the output of gold in that State.

When it is considered that the yield of the placers above spoken of is stated to be one dollar per cubic yard, the introduction of several similar hydraulic plants into the well-known rich mining districts of that State, would open up vast fields of enterprise and pour into the channels of commerce streams of golden wealth. Let, therefore, California look to her laurels and it will be found that the use of these simple and effective machines may destroy the bugbear of the vexing debris problem.

For it will be observed that the plan of operations by the arrangement of the outer flume provides its own dumping ground in the successive stages of working and that vast shallow deposits of rich auriferous gravel with low, outlying ground can be opened, new industries fostered and our State of California made richer within herself.

The citizens of Carson, Nev., are going to try to persuade the authorities to re-open the mint.

Must Stop Mining.

It will be remembered that in the famous "debris" case of Woodruff vs. North Bloomfield and other companies, the Judge decided that all the defendants should be "perpetually enjoined and restrained from discharging or dumping into the Yuba river, or into any of its forks or branches, or in any stream or tributary to said river, or any of its forks or branches, and especially into Deer creek, Sucker Flat ravine, Humbag creek or Scotchman's creek, any of the tailings, boulders, cobblestones, gravel, sand, clay, debris or refuse matter from any of the tracts of mineral land or mines described in the complaint."

It having been alleged that the miners were disobeying the judgment of the court, they were summoned to show cause why they should not be punished for contempt. They denied having violated the order, and the matter was referred to Master in Chancery, S. C. Houghton, to take testimony and find out the facts. In his report, just filed, he says:

"The evidence clearly shows that since the date of the filing of the decree herein, mining tailings have been discharged into Humbag creek by the respondent, the North Bloomfield Gravel Mining Company, from its mines, described in the bill."

He then recites the facts proved by the testimony, showing that what he calls "drift mining" is constantly carried on with large quantities of water; that in one place a 15 inch monitor is in operation, and that the company uses on an average 1000 miner's inches of water per day, and concludes by saying:

"I therefore find, and do report that since June, 1884, the North Bloomfield Gravel Mining Company, respondent, has been continuously engaged in practical drift mining in its mine described in the bill herein; that in procuring, facilitating and protecting such drift mining operations, said respondent has removed from its said mine and discharged into Humbag creek, a tributary of the Yuba river named in the decree herein, a considerable quantity of mining tailings; that mining tailings, in much less quantity, have also been by said respondent discharging from its said mine into said creek by means of water run from ditches over the banks of said mine; and thereby said respondent has violated the decretal order of this court, and is in contempt."

A scheme is on foot at Portland to raise a fund for the purpose of encouraging the location of manufacturing enterprises there.

METHOD OF WORKING LOW BEDS OF AURIFEROUS GRAVEL.

Mining Debris.

The Legal Strife Between the Farmers and the Miners—Mistakes Made and Need for Better Methods on Both Sides.

DUTCH FLAT, PLACER CO., NOV. 19, 1885.

EDITORS PRESS:—Sojourning in this place, formerly one of the great hydraulic mining centers of the State, I have had opportunity to notice the effect produced by the closing down of that class of mines, which has been more disastrous here than in most other localities, for the reason that there are not in this vicinity any drift or quartz mines that amount to much. Since coming here I have become more convinced than ever that the farmers and miners made a great mistake in that they did not, at the commencement of their troubles, come together on some common ground and adjust their differences in an amicable way.

While the parties to this contest might naturally be expected to differ in opinions touching its merits, it is, nevertheless, true that this question has been discussed with too much rancor on both sides, and very often with too little regard to exactness in their statements of facts. To illustrate: The farmers and their friends, in estimating the amount of damage caused by the mining detritus, manifest a constant tendency to exaggerate the same, evincing, meantime, an equal willingness to depreciate the benefits resulting from hydraulic mining. So, on the other hand, do the miners and their adherents show a like disposition to underrate the amount of this injury, and unduly magnify the importance of the business in which they are engaged. Not only so, but aside from this disingenuousness, there has appeared so much of misstatement on both sides as amounts seemingly to a willful perversion of facts. There has, to say the least, been a good deal of loose talk indulged in pro and con in the conduct of this controversy.

Many of the miners, for instance, keep on asserting that their opponents intend, after they have prohibited hydraulic operations, to put a stop to all kinds of mining, a statement contradicted by reason as well as by the farmers themselves. The only warrant the miners have for holding and reiterating this opinion is the declaration made by certain extremists among their opponents, to the effect that the anti-debris people will never rest satisfied till the water comes down from the mountains in its original purity; which declaration, were it true, would, to be sure, imply a purpose on their part to put a stop to every form of mining. But as the Anti-Debris Association repudiates this ultra view, it is just as unfair to charge them with entertaining such purpose as it would be to charge the Miners' Association with the design of enjoining the farmers from plowing their land, as has been suggested by some of the miners, on the ground that stirring up the soil over areas so vast sends down more sediment into the rivers than comes from the hydraulic washings; and yet no sane person can for a moment suppose that the association or the great body of miners favor any such movement, or ever harbored a thought of the kind.

A Strange Misapprehension of Facts.

Misled by this language of hyperbole and so much reckless asseveration, many persons, not the special adherents of either of these parties, have come to entertain rather vague and sometimes very erroneous ideas about this whole business. You will, for example, meet with otherwise well informed people who are impressed with the idea that a large proportion of the farming lands in the State has been destroyed by the mining detritus, and that much of the balance is threatened with a like fate unless hydraulic operations are wholly arrested, to say nothing about rivers turned from their beds, towns buried up and harbors already shoaled to a dangerous extent. So, too, you will meet with others who speak of gold mining in California as being a thing of the past, they being under the impression that the check put upon hydraulic operations in the central counties of the State has about depopulated the mines and extinguished the whole business, these people not being aware that hydraulic washing is still permitted to go on and is never likely to be interfered with in the northwestern counties, and that never so much as one-half the gold product of the State was obtained from the hydraulic mines. Since the closing of so many of these mines, including all the larger ones, the contributions from this source are, of course, much less than before, amounting now to not more than a million dollars against six or seven millions formerly. As regards the quantity of land destroyed or ever likely to be destroyed, by the mining debris, its disproportion to the entire tillable land of the State is as one to one thousand.

And so, through such wide misconception of the real facts, the public mind has been abused, many persons having been led to prejudice the case accordingly as it happened to be first presented to them by one side or other, while the parties to the controversy influenced by these

extreme views have been all the while drifting further and further away from each other.

A Case to be Settled by Concessions and Compromises.

If there ever was a case that required to be treated in a spirit of conciliation and fairness—in which the rights and grievances of both sides should be considered and duly weighed, this is one. To such extent is it burdened with hardships and balanced with equities that, if ignoring the complaints of one party we listen only to those of the other, our feelings are strongly enlisted in behalf of the latter, whereas a dispassionate hearing of both sides leaves our sympathies divided and our judgment in doubt. Even the judicial mind, perplexed and confounded, has felt constrained, to qualify as much as possible its findings in view of the much conflicting evidence before it, and the absence of statutory provisions and decisions precedent to guide it.

Evidently, then, if the questions involved in this contest are ever to reach such settlement as will stop further litigation and strife, it will have to be done by compromise, even though such disposition of them fail to fully satisfy either party. There will have to be concessions made—something yielded and something tolerated on both sides. The valley towns and the land owners will have to bear with a little inconvenience and even suffer a little injury; the miners will have to go to the heavy expense of impounding or otherwise taking care of the more damaging portions of the debris, while the State and the General Governments will each have to contribute something towards protecting the water ways and incidentally the towns and farming lands along them. The above outlines the policy that it seems to me ought to be pursued, this being the idea I have entertained from the beginning of this trouble.

What Should Have Been Done at the Start.

After having visited and examined the Bear and the Yuba river bottoms, while acting as Secretary of the Hydraulic Miners' Association for the first few months after it was organized, I suggested to the members of that body that it might be a good plan for them to buy up the damaged lands along these streams and convert them into a grand dumping ground, leveeing the river banks at the same time and building retaining dams at all eligible sites below the mines. Up till that time there had existed mutual good feeling between the farmers and the miners, each showing a disposition to co-operate in the adoption of preventive measures, in the furtherance of which Yuba county had already contributed over \$30,000 towards the construction of levees along the Yuba. Had some such policy as this been pursued at the start, the costly litigation that has since followed might, and very likely would have been avoided, while the farming lands and the navigable streams would have been fairly protected and the miners allowed to continue their operations with little or no interruption. It is much to be regretted that some such amicable arrangement was not then reached, nor is it easy to see how there is to be opened, even at this late day, any very different way out of these difficulties.

How It Works in the Mines.

Without going over the grounds so often traversed in the discussion of this subject, let us examine for a moment and see how the stopping of hydraulic washing is affecting individual interests and the general welfare here in the mines. Confining our observations, for the nonce, to a few cases, two of them consisting of hydraulic mining, and two of other branches of business not conducted by the hydraulic process but dependent upon it, the one for its existence and the other largely for its support. And that I may not seem partial I will pick up these examples in different places in the neighborhood and quite at random.

James L. Gould,

A resident of this place, has been engaged in hydraulic mining in Gold Run, three miles below here, for more than 25 years, having commenced when quite a young man and grown up with the business. Mr. Gould has always been noted for his energy, enterprise and business capacity, qualities that enabled him to buy out his partners one after another, until he became the principal owner of the Gold Run Company's extensive properties, consisting of ditches, reservoirs, water franchises, and a large area of valuable mining ground. Much of the top dirt having been run off from this ground many years ago, it became necessary to drive a system of bed rock tunnels in order to reach and effectually handle the remaining stratum of rich, cemented gravel: a work which Mr. Gould, having commenced some 10 or 12 years ago, only completed after a series of years spent in unintermitting effort, and at an expenditure of nearly \$100,000. In driving this system of tunnels, which comprised a main trunk and several branches, Mr. Gould was the first to introduce the power drill on this coast, demonstrating its utility in the prosecution of this kind of work. Having incurred such heavy expenses, besides large sums laid out in otherwise improving his plant, Mr. Gould had been running only a few years when he was enjoined from further operations, he having been the first party proceeded against by the Anti-Debris Association. This action against the Gold Run Company was, in fact, brought by the association with a view to making it a test case. That the debris then being run off by this company could little harm any property or interest below may be inferred

from the fact that they were working the hard bottom gravel, every pound of which had to be blasted out with powder and the fragments further pulverized before it could be washed at all. These tailings, were, therefore, not only limited in quantity, but were so heavy that they could not travel far after their escape from the sluices. Although comparatively little of this hard gravel could be handled, it paid well, being very rich in gold; and Mr. Gould was beginning to realize some return from his heavy outlay with a prospect of ultimate large profits, when the hand of the law coming down heavily upon him closed his works, and, cutting off his revenues, left him encumbered with a considerable debt besides.

Thomas Wheeler,

Having amassed a handsome fortune mining for nearly thirty years in Sierra county, came some seven or eight years ago to Little York, two miles from this town, and there with his family, invested all his means in the hydraulic mines at and near that place. For constructing headrock tunnels and making other needed improvements, Mr. Wheeler had to encumber his property somewhat; but for all this, having gotten his claims into good shape and being himself an experienced and thorough-going miner, he was in a fair way not only to make money but achieve a large success, when the courts interposing, put an end to his operations; which interposition leaves Mr. Wheeler in his old age with a family on his hands and about penniless.

William H. Kinder,

Living at Gold Run, three miles southwest of this place, is another old-time hydraulic miner, having been among the very first to engage in this style of gravel washing. Mr. Kinder has, moreover, distinguished himself for the many valuable improvements he has introduced into the business, he being the inventor of the very effective gold-saving appliances known as the "Undercurrent" and the "Secondary." He was also the first man in California to rig up and work on a large scale what are known as tailing or canyon claims; one of which, outlitted by him on Canyon creek, was not only the best appointed, but by far the most extensive claim of the kind in the State. This claim being dependent on the hydraulic mines at Gold Run for its supply of material, was rendered worthless by the closing down of those mines. Prior to, and perhaps anticipating that event, Kinder had inaugurated a similar enterprise on Bear river, where, diverting the tailings as they gradually worked down stream, he passed them over a series of undercurrents, by which they were made to yield up very nearly all the gold they contained. But here again this most useful and persevering man was doomed to meet with a further, and what proved to be a final and crushing disappointment, the stopping of hydraulic washing above on Bear river, having here, as over at Gold Run, cut off the supply of tailing, leaving the costly, but now unproductive plant on his hands and his means exhausted.

Turning now to the east, two miles off that way stands

The Great Lumber Enterprise of the Towle Brothers.

In which something like half a million dollars must have been invested: the plant comprising several large saw mills and nearly 20 miles of railroad, besides vast tracts of magnificent timber land, patented and paid for. Now, this firm, while they have marketed much of their lumber at more distant points, have always depended largely on the hydraulic mines, of which there are a great many within easy reach of their mills, these mines having in times past taken fully one-third of their entire product. With the cessation of hydraulic operations, so much reducing the consumption of lumber, this firm have curtailed their labor force to a corresponding extent, thereby throwing a good many men out of employment and causing much distress in the lumber regions. While the Towle Brothers are not the men to succumb to any slight reverse of fortune, they nevertheless feel this loss of patronage severely, inasmuch as it renders a good deal of their heavy investment here nonproductive.

And so, everywhere throughout the enjoined districts, the shutting down of the hydraulic mines has affected a wide range of other interests and industries besides those directly concerned. The several foregoing cases are merely typical, each of a class, and do not include all or even a quarter of those that might be cited in this immediate neighborhood. Within a mile of the town not less than five or six large hydraulic mines have been closed by injunction, two of them belonging to Eastern parties, who purchased them not long since from Alvinza Hayward, who is himself still a loser to some extent by the closing down of the hydraulic mines elsewhere in the State. It is true he can stand it, but should there be forced upon one who has done so much to promote legitimate mining any more losses than are absolutely necessary? To gratuitously jeopardize the investments of a man like that is highly impolitic, as tending to discourage him from aiding mining enterprises hereafter. The losses sustained by Egbert Judson from the same cause amount to between thirty and forty thousand dollars per year, his investments being mostly over on the San Juan divide; and Judson is another man who has done something towards promoting the industries of California: as much, perhaps, as any man who ever lived in the State. His pecuniary interests should not, therefore, be needlessly sacrificed.

And what is to be seen here at and about Dutch Flat must be multiplied many times to measure the sum total of injury that has resulted from the shutting down of the hydraulic mines; all which takes us back to the starting point, to wit: the much hardship involved on both sides of this question, rendering it one eminently fit to be settled by a yielding and conciliatory policy, both parties conceding and suffering something, the farmers a little and the miners a good deal.

HENRY DEGROOT.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

GRAIN SEPARATOR.—James M. Smith, Etua, Siskiyou county. No. 329,602. Dated Nov. 3, 1885. This improved grain-cleaner consists in a combination of devices. There are two grain-carriers or belts having tight or closed surfaces for carrying all the grain or straw and arranged one below the other in different inclined planes, so that a drop is obtained from the discharge end of one to its receiving end of the other. The invention also combines in a threshing machine, with the riddle through which the grain is sifted or falls, a shoe bottom having an inclined flow adapted to receive this clean grain and discharges it into a conveyor; and with this an oppositely inclined flow adapted to receive the dirt and trash and discharge them into a separate conveyor.

EXTENSION BABY CARRIAGE.—Anthony McLean, S. F., No. 329,579. Dated, Nov. 3, 1885. The invention relates to that class of children's carriages that are adapted to be readily converted into other forms of receptacles or devices, according to the necessities of particular times; and the invention consists in the arrangement and construction of the running gear, carriage body and various attachments. The whole body of the buggy is adapted to be extended or contracted, and the carriage-body may be adjusted to different angles to the front of the carriage on account of wind or sunshine, as the case may be.

LAMP CHIMNEY CLEANER.—Mortimer D. Lamb, Butte City, Montana. No. 329,571. Dated Nov. 3, 1885. This invention relates to a new and useful lamp-chimney cleaner of that class in which hinged sections are provided with suitable rubbing surface or material curved to conform to the interior of the surface of the chimney, and adapted to be inserted and rotated or turned in the chimney, or the latter turned on the cleaner. The invention consists in a peculiar folding double cleaner, which folds up, which is adapted to open out to form a continuous plane, with springs to facilitate the folding.

WASH-BOILER.—Martin F. C. D. Dannmeyer, S. F. No. 329,628. Dated Nov. 3, 1885. This is a wash-boiler in which clothes are cleaned by the operation of a continuous stream of hot water. It consists of an outer inclosing case or boiler, and an interior diaphragm formed with double walls and top, with a filling of non-conducting material, the diaphragm resting upon the bottom of the outside boiler, and having a space beneath it and passage by which the water may pass from above into this space, with directing plates and upwardly extending pipes whereby the circulation is maintained.

WINDMILL.—Edward Gilman, Oakland. No. 330,014. Dated Nov. 10, 1884. This improved windmill consists of a vertical shaft, having arms projecting horizontally from its upper end with wings supported upon vertical shafts journaled in the ends of the upper and lower arms, and connected with a central tail-supporting shaft by gearing, so that the position of the wings or sails will be regulated by the direction from which the wind blows. These sails are arranged so as to automatically adjust themselves to the intensity of the wind.

MOTOR FOR CARS AND VEHICLES.—Leonard C. Pressley, San Francisco, No. 330,151. Dated Nov. 10th, 1885. This motor for cars or vehicles consists of a frame-work supporting a series of guides which may be so tilted as to stand in a vertical position, with their ends downward, and a series of weights which slide upon these guides, and are connected with a central shaft by cords or gearing, so that as they movedown these guides their power will be applied to this shaft, and by an intermediate mechanism this power is communicated to the traction-wheels of the vehicle. Various mechanisms may be used for reversing the frame-work and guides carrying the weights, such as worm gear, etc.

FORMING CORES, MODELS AND CASTINGS.—Richard Savage, S. F. No. 329,958. Dated Nov. 10, 1885. This invention relates to machines for forming cores of sand by impacting the sand around a bar or mandrel. The inventor has a rotary core, bar or mandrel, with a hopper and a telescoping spout, having its discharge openings equal in length to the mandrel, and on the same vertical plane therewith. One claim of the patent covers "a means for forming cores or molds for castings consisting of a receiver or hopper, having an opening in the bottom, a directing-chute extending downward from said opening, and a supplemental section sliding upon the chute so as to be made longer or shorter."

MECHANICAL PROGRESS.

Manufacturers and Machinery.

Men who conduct great business enterprises are naturally conservative and averse to innovations and experiments. And yet it is through experimental knowledge, acquired by reducing theory to practice, that all progress in the useful arts is made. But it is not the business of the purely practical man to theorize; he is concerned only with actual results, and adopts those means which he finds ready-made to his hand, and which he thinks are best calculated to produce these results. The field of scientific speculation, in which the investigator reasons from cause to effect, and applies well-known principles, and the laws of matter in working out those mechanical problems which relate to production and industry, belongs exclusively to the inventor. He is the manufacturer's best friend and benefactor, and yet he is sometimes regarded by the latter almost in the light of an enemy, because he is the instigator of changes and innovations, because he will not let "well enough" alone, but is continually coming forward with some new mechanical device or machine in the line of improvement, which revolutionizes the existing order of things, and which the manufacturer is compelled to adopt. Hence there are many fossilized mill-owners who dread the appearance of the inventor with his new machines, as the sick man dreads the potion of physic or the surgeon's knife which is to cure his infirmities and give him a new lease of life. He would rather he let alone, and plod along in the same old beaten track which leads to no progress, provided his contemporaries in the same line of business are content to do the same. Even if it can be demonstrated that the new invention is one in the interest of true economy, and will pay for itself ten times over in the course of a few months, he is reluctant to investigate its merits, and don't care to experiment with it. He can only be interested on compulsion. Especially if its adoption would involve any considerable immediate outlay, he can't see any good in it, and won't touch it until compelled to do so by the action of some more enterprising and progressive rival, who "knows a good thing when he sees it," and who believes that "the best is the cheapest" in the long run. It is undoubtedly true that the continual improvements in machinery involve frequent changes, which are sometimes expensive and burdensome to manufacturers. But on the whole, the latter, as well as the great consuming public, are large gainers by these changes, on the score of improved processes and cheapened production.

In this age of progress no producer of textile, leather or metal fabrics can afford to ignore any new device or invention which secures the best results with the greatest economy of time, labor and raw material. In the race of trade competition he will be forced to take hold of these new things sooner or later, and he had better be among the first than the last to take advantage of them. Of course we do not recommend the practical manufacturer to grasp at every new patented machine which comes along, regardless of merit. While open to conviction, and ready to investigate, he also needs to be cautious, deliberate and discriminating in his action, in order to be sure to get the best, and not throw away his money on mere pretentious and catchpenny devices. There is no danger of his being deceived or imposed upon if his investigation is properly conducted. He is not called upon to take the word of any man, however well known or expert in machinery, as to the merits or capabilities of any new specialty. A mere guaranty of certain results should hardly satisfy him. It is not unreasonable for him to require the proof, the practical ocular demonstration, and the owner of any really meritorious patent will never shrink from the real test, however rigorously applied; but after the demonstration is complete, and its utility is established beyond doubt or question, there should be no holding back, if terms are reasonable, on the part of the buyer. A new and good thing in the machinery line, which is really wanted and needed by manufacturers, will not long go a-hogging for customers.—*Manufacturers' Gazette.*

COMPRESSED STEEL.—Further tests of the new French treatment of steel for rendering it tough appear to confirm its value, imparting to it also a fineness of grain, an increased hardness and a notable accession of strength to withstand rupture, this effect being most marked in the case of highly carbonated steel, and in this respect the metal is made to resemble tempered steel, without being in all points identical with it. The cause of this alteration in physical condition is attributed to the rapid heating and no less rapid cooling of the metal; that is, when the red hot steel is first strongly compressed, which is the peculiar feature of this process, the conversion of the mechanical energy into heat serves to raise the temperature of the entire mass at the same time that the particles of the metal are more closely cemented together; this effect is followed by a rapid cooling, due to the contact of the plate of the hydraulic press with the surface of the metal, and the very close pressure materially increases this conducting effect of the cold metal.

NEW MECHANICAL CONSTRUCTIONS.—However correct the original designs of a complicated machine appear on paper, practical experience

teaches that small modifications are required in the details, before perfect accuracy of action is secured. Capitalists who engage in the manufacture of, or invest in new devices, and do not take into account the delay and expenses due to this cause, find their estimates sadly out of gear. It is seldom that even the simpler mechanical inventions, when essentially different from machinery previously in the market, work to entire satisfaction at once, even if the more skillful designers have made the plans. Many a fabulous profit, expected to be realized already within the first year of the investment in this special mechanical device, is wrecked on this shoal, or is at least seriously diminished in its proportions. Of course men of experience always realize this risk, and make some kind of allowance for it; but those who invest widely in engineering devices, and especially the novices, have their tempers not a little ruffled by this experience, and are too ready to blame the engineers and machinists for what seems, in the nature of things, to be an inevitable accompaniment to the manufacture of essentially new mechanical constructions.—*Am. Engineer.*

An Improvement in Glass Manufacture.

It is said that an important discovery has recently been made in the manufacture of glass, which bids fair to revolutionize that art as completely as the character of the iron trade has been changed in its methods by the introduction of processes for making steel cheaply on a large scale. It is in effect that any desired degree of hardness, within a rather wide range, may be communicated to glass, and that by very simple means. It is nothing more than the equable distribution of heat through the mass, and then an equable cooling. The discovery is credited to Frederic Siemens, and a full account of the process appears in the current number of *Science*. The difficulty of heating and cooling glass at an equal rate throughout is the great stumbling-block that has stood in the way of success. Without this the material was liable to crack or explode, a familiar illustration of which is furnished in the breaking of a tumbler when hot water is poured into it, the danger of fracture increasing with the thickness of the glass. The application of radiant heat overcomes the first half of this difficulty, and the second is obviated by surrounding the edges with a material that prevents the heat from leaving them more rapidly than that from other portions. By placing the glass between plates of suitably prepared metal, the softened substance can be embossed with any wished-for design, and after leaving the mold it is four or more times as hard as ordinary glass, being, in fact, so "firm" in its substance, that the diamond fails even to scratch it. Hence, it must be made to exactly the size and shape wanted, but after having been so made it is at least three times as strong as ordinary glass of the same thickness, and appears to be even less liable to give way on account of flaws than is cast-steel.

Castings have already been made of floor-plates, grind-stones, pulleys, railroad sleepers, etc., and it is believed that its use can be indefinitely extended to many of the uses of wood and metal in the arts, and especially in the building trades. Nothing is said of the cost of the new glass, which is a most important point in determining the extent to which it will be employed for the purposes above noted. But at the first blush it would appear to be capable of being produced much more cheaply than its equivalent in iron or steel. It consists of about 15 per cent of potash, 75 per cent of silica (sand), smaller quantities of lime and alumina, and traces of other material. All of the articles named except the first are literally "as cheap as dirt," and potash is not very costly; while the quantity of fuel required is probably less than that needed to reduce the ores of iron to the metallic form. Hence it is not impossible that many of those now living will see the time when people will reside in glass houses, and not be more afraid of throwing stones than if they tenanted structures made of ordinary bricks and mortar.

A NOVEL LOCOMOTIVE.—A new locomotive that promises good results in economy is undergoing trial on the Pennsylvania railroad, says the *Philadelphia Press*. It is known as the Coventry engine, named after the inventor, a Chicago man. Outwardly, except that the smokestack is close to the cab, there is nothing to distinguish it from a common locomotive. The novelty is in the boiler, which has a return flue, thus doubling the length of the tube, and considerably more than doubling the time of the retention of the heated gases within the boiler. As the heat in the return flue has been frequently tested at between 1100 and 1200 degrees, the inventor claims that it is better to utilize it than to let it escape like a rifle shot from a straight tube. He claims also that the length of the tube insures the consumption of much gas and smoke that must otherwise escape, and that cinders are precipitated by gravity, so that not only is provision made by the invention for the maximum of steam, but for the minimum of dirt. It is a bituminous coal engine. Mr. Coventry says that the engine can be run at a saving of at least 15 per cent under other engines of its kind, and is cleaner than any other bituminous coal engine can possibly be. He hopes to have the boiler adopted in any engines that the road may build, both for freight and passenger service. The railroad officers admit that the engine is cleaner than the others that use bituminous coal. The claim of economy will be fully tested within a week or two.

SCIENTIFIC PROGRESS.

The Life and Age of Fishes.

Every few years the papers are flooded with paragraphs announcing great and sudden mortality among the fishes on some portion of our seaboard. We not infrequently meet with such headings—"A fish pestilence in the gulf," or "The sea covered with dead fish," etc. Sensational as such notices may appear, they are not at all exaggerated. As far back as 1844, on the southern Atlantic Coast of the United States, there was a great mortality among the fish in that region. Ten years later, in 1854, a similar occurrence took place. Again, during the three successive years of 1878, '79 and '80, large numbers of dead fish covered those waters for hundreds of miles in extent. In the winter of 1881-2 a most unusual mortality occurred along the middle Atlantic Coast. It was during this period of fish mortality that the extermination of the newly discovered, deep water "tile fish" occurred. This fish, it will be recollected, was discovered by the Fish Commission in 1879, and large commercial profit was expected to be derived from their catch. Careful search has been made for these fish since that time, but without success.

Many theories have been put forth to account for these phenomena, such as "poisoned water," "extreme cold," "earthquake shocks," "submarine eruptions of gas," etc., but nothing has been advanced as yet which appears to be acceptable to careful students of this problem. There are many other phenomena connected with fishes, such as the sudden disappearance of certain varieties from their accustomed haunts, and their re-appearance as suddenly in other localities. Then again, the total absence of certain fishes from haunts where they have been present in vast numbers for many years, and their re-appearance in equal numbers 10 or 15 years later. These phenomena deserve careful study at the hands of competent students.

The Age of Fishes.

It is not generally known, says a recent correspondent of the *New York Herald*, that there is hardly any limit to the age of fish. Prof. Baird of the U. S. Fish Commission is authority for the statement that there is authentic evidence to show that carp have attained an age of 200 years. Prof. Baird also says there is a tradition that within 50 years a pike was living in Russia whose age dated back to the 15th century. "There is nothing," says he, "to prevent a fish from living almost indefinitely, as it has no period of maturity but continues to grow with each year of its life." There are gold fish in Washington that have belonged to one family over 50 years. They do not appear to be much larger than when they were first placed in the aquarium, and are quite as lively as when they were young. There are so many fish stories in circulation that the ordinary reader has almost made up his mind that fish and truth do not go well together. Probably some persons will doubt what is said by Professor Baird about the age fish can attain. If they do they are simply doubting the best known authority on fishes. The Russian minister at Washington says that in the royal aquariums at St. Petersburg there are fish to-day that are known by the records to have been in those same aquariums for 140 years. Some of them are, he says, over five times as large as they were when first captured, while others have not grown an inch in length. An attaché of the Chinese Legation corroborates this statement. He says there are crocodiles kept in some of the palaces in China that are much older than any of those in Russia.

THE MOST WONDERFUL THING IN THIS WORLD, aside from a man, is a book, and the great wonder is that so few people read books. We call ourselves a reading people, and so in a sense we are, but there is very much of the reading enjoyed in these times that is to no purpose. You can find some kind of reading matter in every home, but very often it has been selected without regard to its worth. The books may have been bought because they were pressed upon the purchaser by an agent, or because of the binding, or the pictures, or the number of pages. There are not in any communities very many good private, and very few public libraries. The great mass of people are more concerned about getting rich or keeping up with the fashion than in feeding the mind and keeping up with the times. A taste for good reading is worth more to a young man or woman than the best farm, or the best start in business without it. A man's life is measured not by the abundance of the things he possesses, but by the volume of soul that he has. The Chautauqua literary course covers a wide field, includes a most excellent selection, encourages a system in reading, and should be entered into by every young person who cares for the cultivation of his mind.

IRON AND STEEL CRYSTALS.—An exchange says that the microscopic determination of the different qualities of iron and steel is now regarded as one of the most valuable aids in metallurgical industries. Thus the crystals of iron are double pyramids, in which the proportion of the axes to the bases varies with the quantity of the iron; the smallness of the crystals and the height of the pyramids composing each element are in proportion to the quality and density of the metals which are seen also in the

fineness of the surface, and as the proportion of the carbon diminishes in the steel the pyramids have so much the less height. In pig-iron and the lower qualities of hard steel the crystals approach more closely the cubic form. Forged iron has its pyramids flattened and reduced to superposed parallel leaves, whose structure constitutes what is called the nerve of the steel; and the best quality of steel has all its crystals disposed in parallel lines, each crystal filling in the interstices between the angles of those adjoining, these crystals having their axis in the direction of the percussion they undergo during the working. Practically, good steel has the appearance, microscopically, of large groups of beautiful crystals.

PHOTOGRAPHING THE INTERIOR OF GUNS.—Experimenters have been made at the Royal Gun Factories, Woolwich, in order to test the application of a new electric lamp designed for making examinations and photographs of gun interiors. This system of summarizing the bore of guns by means of electricity has only been a short time in use, and has proved of great value, but the want of an electric dynamo has prevented its general adoption at many places where it would have been of considerable use, and the authorities have now taken up readily a portable battery designed by Johnson & Phillips for the purposes of supplying the place of a dynamo in such cases. The battery without having necessarily powerful, is chiefly serviceable on account of its compactness, as it can maintain a light of unerring brilliancy for inspection, with all the lights they may desire. The experiment was to try the battery and a dynamo in competition. Two eight-inch guns were placed side by side in the new boring mills, and photographs were taken of their interiors by both processes, the results, so far as could be judged, being equally satisfactory.

MECHANISM OF THE BEE.—An investigator into the mysteries of animal life asserts that a bee's working tools comprise a variety equal to that of the avers mechanical. He says that the feet of the common working bee exhibit the combination of a basket, a hrush, and a pair of pincers. The brush, the hands of which are arranged in symmetrical rows, is only to be seen with the microscope. With this brush of fairy delicacy the bee brushes its velvet robe to remove the pollen dust with which it becomes loaded while sucking up the nectar. Another article, hollowed like a spoon, receives all the gleanings which the insect carries to the hive. Finally, by opening them, one upon another, by means of a hinge these two pieces become a pair of pincers, which render important service in the construction of the combs.

SENSE OF COLOR IN ANIMALS.—J. Gruber has investigated the sense of color and illumination in animals. To decide whether animals had a sense of color or of light, he placed them in a box so arranged that qualitative rays fell on one or the other of its two divisions, which communicated with one another. Five mammals, seven birds, two reptiles, three amphibians, two fishes, three molluscs, 27 insects, two spiders, and two worms were experimented with. It was found that the sense of color, as well as the power of perceiving light, was much more widely distributed among animals than has been generally supposed. The variations in the sense of color in various animals are very great, but a much greater number of observations must be made before a definite solution of the problem can be obtained.

ORIGIN OF THE LOMBARDY POPLAR.—According to Mr. Bossier, a botanist who has lately studied Oriental botany, this poplar is a distinct species, which he calls *Populus pyramidalis*. It is believed by the best authorities to have originated in Persia. Some writers, on the other hand, state that it is truly indigenous to Italy, but the evidence, however, we think, is strongest in favor of Persia, from whence, most probably, it was introduced into Italy, where it is now a favorite tree and extensively grown.

THE EARTH'S CURVATURE.—The question how far an object on the surface of a level plain can be removed from a man before the curve in the earth's surface makes it invisible may be answered as follows: The depression of the curve of the earth's surface is for two miles 2.67 feet, three miles six feet, four miles 10.67 feet, six miles twenty-four feet, ten miles sixty-six feet, and fifteen miles, 150 feet.

THE MEDITERRANEAN ONCE AN ISLAND SEA.—An English geologist thinks he has found evidence that the Mediterranean was at one time shut off from the Atlantic; that it was divided into two distinct basins by a strip of land extending from Italy to Africa; and that most of its islands, notably Sicily and Malta, were connected with the mainland.

SUGAR BY ELECTRICAL ACTION.—New sources of electrical economy appear to be constantly coming to the front. One of the latest is a process for refining sugar by electricity at an expense of 40 cents a ton. The inventor asks \$12,000,000 for the patent. It is said that the process is to be tested in England.

VACCINATION FOR CATTLE.—Pasteur's method of vaccination for cattle plague has proved successful in India for horses, cows, sheep, buffaloes, asses and elephants.

Passing Events.

During the past week we have had constant rains, which have extended all over the State. The rainfall for the month exceeds that of any previous November of which records have been kept. In some places damage has been done and railroad traffic has been impeded, but the general effects of the long continued storm have been of benefit to the State.

The new mill at Candelaria, Nev., for the Candelaria Water and Milling Company has been commenced and will be running in three months. This is one of the signs of a revival in mining matters in that part of Nevada.

The Walker Lake Bulletin takes from the statistics of Wells, Fargo & Co. figures which show that during the twelve months ending Nov. 1st the shipments of ore and bullion from the northern end of the county, including only as far south as Soda Springs, was \$594,000. For the twelve months preceding the amount was \$566,000. During the last year the Mount Cory was a producer for but four months and still the total has increased. This increase arises from the proceeds of the numerous mines which have been opened and worked in the districts along the line of the C. & C. R. R. and as yet includes but little from the new gold mines of Hawthorne district. Mining matters are looking up in that whole region.

Death of the Vice-President.

The sudden death of the Vice-President of the United States was announced by telegraph on Thursday morning. Mr. Hendricks had a very short illness indeed, and such a result was anticipated by no one, not even by members of his own family. Thomas Andrew Hendricks was born in Muskingum county, Ohio, near the city of Jamesville, September 7, 1819, and was therefore 63 years, 2 months and 17 days old at the time of his death. He was said to have been addicted to none of the vices, either great or small, that so often beset public men, and even his political opponents will admit that his walk through life was unusually circumspect. From the time he was admitted to the Bar until his election to the Vice-Presidency he was active in the practice of his profession, excepting only the period during which he was Commissioner of the General Land Office and the four years he was Governor of Indiana. Mr. Hendricks' election to the office of Vice-President of the United States and his inauguration on the 4th of March last are matters of history and require but passing mention. Of his subsequent career and actions it is enough to say that they have, like those of all public men, been severely criticised at times, but no one ever called in question his private or official integrity.

On receipt of the news of the death of Mr. Hendricks, a Cabinet meeting was called, and it was decided that the President and members of the Cabinet should attend the funeral of the Vice-President. When the Cabinet adjourned the President issued the following:

EXECUTIVE MANSION,

WASHINGTON (D. C.), Nov. 25, 1885.

To the People of the United States: Thomas A. Hendricks, Vice-President of the United States, died to-day at 5 o'clock P. M. at Indianapolis, Ind., and it becomes my mournful duty to announce the distressing fact to his fellow-countrymen. In respect to the memory and eminent and varied services of this high official and patriotic public servant, whose long career was so full of usefulness and honor to his State and to the United States, it is ordered that the national flag be displayed at half-mast upon all public buildings of the United States; that the executive mansion and several executive departments in the city of Washington be closed on the day of the funeral and he draped in mourning for a period of 30 days; that the usual and appropriate military and naval honors be rendered, and that on all legations and consulates of the United States in foreign countries the national flag shall be displayed at half-mast on reception of the order, and the usual emblems of mourning be adopted for 30 days.

By the President, GROVER CLEVELAND.
T. F. BAYARD, Secretary of State.

Nickel and Cobalt from Solutions.

Mr. C. H. Aaron, of Nogales, the well-known author and metallurgist, has patented through the MINING AND SCIENTIFIC PRESS a process for separating nickel and cobalt from ore or metallurgical products with which they may be associated. The process consists in precipitating nickel and cobalt from a solution in the form of zanthates or methyl-sulpho-carbonates. The substance is treated in any of the usual ways by means of acid, or by roasting and lixiviation, so as to obtain a solution of salts of nickel or cobalt, or of both, and which may also contain salts of other substances. The solution may then be treated in any usual way for the removal of iron, copper, lead, lithium and silver, if present. It is not necessary to remove zinc, manganese, arsenic, tellurium, selenium, or any earths, alkaline earths, or alkalis which the solution may contain, any or all of which, for the purposes of this process, may remain in the liquid if present therein.

The solution should be neutral or but slightly acid. To the solution thus prepared Mr. Aaron adds an aqueous solution of a soluble zanthate, or the corresponding methyl-sulpho-carbonate may be used in place of zanthate. By this means the nickel and cobalt in the solution are precipitated as zanthate or methyl-sulpho-carbonates, while the other substances remain in the solution, if present. For the purpose described several substances may be used, but the inventor prefers sodium salt on account of its being easily made, and on account of its comparatively low molecular weight. The precipitate is collected and washed, and may then be dried and calcined, yielding the oxide of nickel or of cobalt, or a mixture of both, if both metals be present; or the mixed precipitate may be treated with ammonia be-

fore calcination. The ammonia dissolves only the nickel compound in this case, and the cobalt compound may be collected, dried and calcined. The nickel compound is precipitated from the ammoniacal solution by neutralizing the latter, the nickel compound being then collected, dried and calcined.

Improved Compound Steam Engine.

An improvement has recently been made in this city in steam engines of that class having two or more cylinders of unequal diameters placed with their axes in line, and with the piston connected to one cross-head, or other suitable means for causing their coincident reciprocation in parallel lines, steam being supplied from the boiler to the first or smaller cylinder, from which it is allowed to expand, exerting its final force on the pistons of the larger or remaining cylinders.

In direct-acting engines of this class, not employing a receiver in which to expand the steam in its passage from the high to the low pressure cylinder, a great disturbance of the acting force of the engine is produced by expanding high-pressure steam from the first cylinder direct to the low-pressure cylinder, causing a sudden jump of the engine at the commencement of the stroke or disastrous strains brought upon the connections. To overcome this difficulty, two plans have been resorted to. The first and most common is to make less difference in the relative areas of the pistons, a less ratio of expansion, and in some cases a throttling or wire-drawing device is employed in conducting the steam to the low-pressure cylinder. The effect of this is to limit the possibilities of economy in the consumption of steam by a fixed low rate of expansion or by wire-drawing the steam, with its equally limited results. The second plan is to conduct the exhaust steam from the high-pressure cylinder into a separate receiver or chamber of sufficient capacity to nearly equalize the intermediate pressure, from which it is conducted to the steam chest of the low-pressure cylinder, giving a steady and uniform force to the engine, dispensing with all intermediate throttling devices, causing no limit to the desirable higher ratio of expansion and consequent economy thereof by the construction of the engine, as is the case with the first-mentioned plan.

Mr. George E. Dow, of the Dow Steam Pump Works of this city, an accomplished mechanic and inventor, has patented through the MINING AND SCIENTIFIC PRESS Patent Agency, certain improvements to provide means for a better distribution of the steam than heretofore used in operating engines of this class. In Mr. Dow's new engine there is a receiver surrounding the high-pressure cylinder and connected to the intermediate passage of the valve used for the distribution of the steam. This arrangement embodies the advantages attributed to the second plan referred to, with the addition of increasing the economy of the engine still further by dispensing with the pipes and conduits for the transmission of steam to and from a separate receiver, which usually cause the loss of heat and efficiency by impact and surface conduction, the loss forming a large percentage of the advantage due to the higher ratios of expansion, but not otherwise realized. Live steam from the boiler may be admitted directly to the receiver or the connecting passage of the valve for use at such times as starting up when cold, accelerating the power of the engine in an emergency by using direct steam (non-compound) upon the larger area of the low-pressure piston, in which case the small area of the high-pressure piston is in equilibrium of pressure, exerting no power.

Mr. Dow has applied his improvement to direct-acting engines for operating pumps, the rods or plungers of which are connected directly to the reciprocating parts, and where there is no fly wheel to distribute or equalize force. It may be observed that to apply this invention to an engine of rotative construction, where a crank and fly wheel are employed, the valve may be operated by an eccentric on the shaft in the usual manner of steam engines. The intermediate steam-raising chamber may be reduced in size or removed entirely, maintaining no more than a passage to the port, providing for the use of live steam, when desired, direct to the low pressure piston.

In the operation of this engine, the steam,

after having done part of its work in the first cylinder, is conducted to the low-pressure cylinder, through the valve in the chest, which is surrounded by live steam of a high temperature, and by which means heat is supplied to the expanding steam on its way to the low-pressure cylinder. The expansive power of the steam is improved materially by this means, affecting the economy of the engine thereby, and permitting in an engine of this construction, improved results as a much higher ratio of expansion can be employed.

The distribution of the steam is by means of the valve, and with a single passage only to operate the pistons of both high and low pressure cylinders, with means for operating in conjunction an intermediate steam-reducing chamber, or when said chamber is not needed, facilitating by the same means an independent live-steam connection for use, when desired, to operate the low-pressure piston direct. The low pressure steam is conducted to the piston of the secondary cylinder in a dry and superheated condition and loses none of its heat by coming in contact with the colder walls of a series of pipes and conduits, as is the case in engines of the ordinary compound type when separate steam beaters to pass the steam through are not employed. Mr. Dow has applied improved valve gear, also his own invention, to this engine.

Electric Railways.

Notwithstanding the general expectation that electricity would be utilized on street railroads, so far the experience has been rather discouraging, and while we hear in the public prints that roads are being successfully operated by electricity, when the facts are investigated no satisfactory results are shown. The Cleveland road is often referred to, for instance, as showing that cable and horse railroads will not be used much longer. Yet that road is not a distinguished success. The electrical part of the road is merely a short continuation of certain horse-car lines, and there are only two electrical motors, which run irregularly. They were first put in operation in August, 1884. Only one motor is run at a time, and by no means constantly. The wire for conducting the electricity is below ground and there is a slot through which passes, from the car, a sort of connecting arrangement, so that the current may be brought to the reversing dynamos which propel the car. The electricity is furnished from the same apparatus which runs the Brush lighting system, so they do not know how much of the power of the engine these motors consume.

The road is practically an electric toy, with little appearance of ever amounting to much. For some unexplained reason the motors are run very irregularly and seem to require a great deal of repairing and overhauling.

The Daft motor, which was tried on 9th avenue, New York, was a very light engine. There is a larger and much better one in mechanical arrangement also running. A central rail is used to convey the electricity, and this rail has to be kept highly polished, or it does not answer its purpose. The motor was intended for drawing four cars, but in the experimental trials two were drawn. They started from 14th street, and went along pretty fairly until they came to an up grade, when they immediately slowed down. Of course, on the return, with the favoring grade, they could come at any desirable speed. Only a few irregular trips have been made. The motor weighs about 18,000 pounds; and it is the opinion of engineers that there will be no economy over steam.

One feature worthy of remark is that there is a perfect sheet of fire from the rail, where the brush comes in contact with it, so that the motor will frighten horses at night more than a steam-engine would.

In Baltimore there is an electric road about two miles long, which seems to be doing better than the others. The electric conductor is above the ties. There are two Daft motors, but the trains run on one turn-table, going when they are ready. No data of expenses have been made public.

It seems evident that as far as the motors, etc., now built are concerned, there is not much to hope from electric roads. There may be, of course, decided improvements to come, which may change the whole status; but at present the appliances in use give no promise of as perfect success as has been hoped. There is very

great room for improvement in the whole electric system as applied to railroads.

The popular impression about these roads seems to be that the cars follow a great magnet. Few people have taken the trouble to inform themselves about the details, and there is much ignorance on the subject, even among educated persons. In the first place, the dynamos to generate the electricity must be operated by steam engines, and the electrical currents carried by wires or rails along the length of the roads, and must be transferred by suitable means to dynamos running reversely on the motors. These must be geared down to the driving wheels in order to get motion. The steam engine furnishes the power in the first place, and many think that the direct action of the steam engines will always be more economical and economical than through the medium of electricity.

Of course, it cannot be foretold what will be effected in time to come. Now, an electric motor that weighs 18,000 pounds will draw just the same load as a steam engine weighing 18,000 pounds, and can draw no more. When the track is wet there is much loss of power. The electric motors have had very exhaustive trials, but it is a significant fact that at no one place in the United States are roads constantly operated by them. At Baltimore it has cost them \$10 for every five cents collected. Some of the roads seem to have been organized more for selling stock than anything else, from appearances.

The Late A. C. Knox.

On the 9th inst., Mr. A. C. Knox died at Lone Pine, Inyo county, while on duty as agent and traveling correspondent of the PRESS. Mr. Knox has been in the employment of Dewey & Co., publishers of the PRESS, for over 20 years almost continuously. He was, for a number of years, our city agent, and as such was well known among San Francisco business men. Afterward he resumed traveling through the interior of this and neighboring States, and has visited nearly all the agricultural and mining sections of any importance. During his many extended trips he has collected a vast amount of information concerning the resources of the various regions. The publication of his letters has been of benefit to the localities described, and to the subscribers of the PRESS.

Mr. Knox was a highly educated man and an intelligent observer. After graduating from college he became a theological student for a year, but finally became a teacher, and was professor of Latin and Greek in an Eastern college for some seven years. He was a constant reader and student all his life, such time as he could spare from his active business being passed, as much as possible, among books.

The fact that he was employed by one firm for so long a time as twenty years would alone show that Mr. Knox was honest and upright. During that time he has attended to collections and other work connected with the business department; and it is pleasant to be able to say that he proved himself a man of the strictest integrity. Somewhat modest and retiring in disposition, he was at the same time of a genial nature and well liked by all who knew him well.

Mr. Knox had been ill at Lone Pine for some weeks, and his son, Charles H., went from San Luis Obispo, and was with his father when he died. Circumstances prevented the remains being brought here, so that they were interred at Lone Pine. Mr. Knox leaves a wife, who is a resident of this city.

Thousands of our subscribers will remember our late business associate, and many will miss him almost as an old friend. He had a wide acquaintance, as might be supposed. Before coming into the employment of Dewey & Co. he was a resident of Virginia City, and for a time of Sacramento. Mr. Knox was a man of independent thought and one who kept in the van of intellectual progress. His father was a resident of a slave State, and it is told of him that he voluntarily freed his slaves, and more than that, made provision for them so they could get on by themselves in free States.

A memorial service will be held on Sunday, Nov. 29th, at the Presbyterian Church on Larkin street, near Pacific. Rev. Dr. Eastman, the pastor of that church is a graduate of the college with which Prof. Knox was formerly connected.

A New Shaft Coupling.

We herewith present an engraving of a new style of shaft coupling, which was designed and made at the San Francisco Tool Works. These couplings are a new modification of the old English muff coupling, which has been in use 60 years, with this difference: the metal is disposed in two shells instead of one, and the clamping screws are placed in the annular space between the shells. The Tool Company have exhausted the whole field of "ingenious" couplings, wedges, sleeves, cones, taper-screws, eccentric bushes, etc., and condemn them all for withstanding heavy, constant strain on shafts not in line.

The makers claim for these California made couplings that they are uniform and interchangeable; can be removed without disturbing a shaft; are fastened or removed with a common

A CALIFORNIA-MADE SHAFT COUPLING.

screw key; have no projecting parts; can be employed as pulleys to drive machinery; are four diameters long and stronger than the shafts.

This is simply a strong, simple "muff" coupling, consisting of two principal pieces only. There are no concealed screws or wedges, taper

Fig. 1.

HYDROSTATIC DOUBLE CONNECTION LUBRICATOR.

bushes, or internal screw threads. Its construction and application are readily seen from the engraving.

THE Los Angeles Herald says: In addition to the little quartz mill running near Alpine Station, and making a good profit, another five-stamp mill has been brought from San Francisco and landed at Ravena, from which place it will be taken to a gold ledge in the Charlotte district, near the Tujunga canyon not far from the old mill erected a few years ago.

THE teredo, so destructive on San Francisco bay, is almost unknown at Vallejo and on Carquinez straits. Piles driven in a wharf at Martinez in 1852 are still intact. This is due to the presence of so much fresh water from the rivers. Wherever fresh water occasionally comes the teredo cannot flourish.

THE Plumas Eureka Mining Company paid in London on the 9th instant a dividend of 37½ cents a share, aggregating \$52,734, making a total of dividends to that date \$1,846,331.

A Michigan Lubricator.

Engravings on this page illustrate the Michigan lubricator, several sizes and styles of which are made for various descriptions of work. Fig. 1 shows the hydrostatic double connection lubricator. This cup will show for itself its simplicity of construction. It has a glass gauge which shows at all times the quantity of oil in the cup, and sight feed glass which shows how fast the oil is being used; drop by drop passing up to the parts to be lubricated. It requires no attention and is always positive in its feed. Referring to the letters on the cut, A is the oil reservoir; B, condensing chamber; C, valve to shut off steam from sight feed, in case the glass breaks; also to regulate pulsation; D, visible feed chamber; E, oil filling plug; G, valve to draw off water; H, steam pipe; I, glass gauge, indicating amount of oil in

cup; J, oil discharges to connect with steam pipe; O, valve to regulate feed of oil; W, valve to admit water into reservoir.

The company manufacture these lubricators in large quantities, and dealers in brass goods and steam fittings will find it to their advantage to open a correspondence with the

Fig. 2.

PORTABLE LUBRICATOR.

the agent. The lubricator is made with double connection.

Fig. 2 shows the portable lubricator, and special attention is called to this lubricator, of which the subjoined cut is an illustration. This is specially designed for small engines, threshers, steam pumps, etc., and is manufactured with reference to transportation over rough roads.

These lubricators are made in capacity to hold half-pints, pints, half-gallons and gallons. They are finished in brass or nickel-plated, as desired. Messrs. Parke & Lacy, of this city, are agents for the Pacific Coast.

THE plan for the extraction of carbonate of soda from the water of Owen's lake by evaporation has proved a success, and more extensive works are to be erected.

THE workmen in the railroad yards at East Oakland are busy getting out the material for a permanent bridge across the Colorado river at Yuma, A. T.

Superintendent or Manager of Mines.

The county of Lake in this State sued the Sulphur Bank Quicksilver Mining Company for irregularities in making its "statement" of property, etc., subject to taxation, and when a decision was against it, took an appeal to the Supreme Court. Without considering all the grounds, some of the points made in the decision of the Supreme Court, on the appeal, are of interest to all mining companies. These points, which we take from the decision, are as follows: The assessment put in evidence shows property assessed to "Sulphur Bank Quicksilver Mining Company, F. Fiedler, agent." It is contended for the appellant that from this it can not be told whether the assessment is to the mining company or to F. Fiedler, or to agent. We think there is nothing in this point. If the same question was put to any one with ordinary sense in the business walks of life, he would have no difficulty in understanding that the assessment was to the Sulphur Bank Quicksilver Mining Company, and that the reference to F. Fiedler, agent, was only to him as agent of the company. We think the same common-sense view should be taken by the Judges.

It is insisted that certain of the descriptions of real property found in the assessment are radically defective. But all the descriptions were taken by the Assessor from a list furnished him by Fiedler, who was the superintendent of the defendant company. It is said, however, that the statute—Political Code, Sections 3629 and 3630—requires that the statement of the property of a corporation must be made by its President, Secretary, Cashier or Managing Agent, and that Fiedler was neither of these; that he was only superintendent, and therefore, not authorized to furnish the list to the Assessor. The only difference we can see between the "managing agent" and "superintendent" of a mining company is one of name. We therefore conclude that he was not only authorized, but required, upon demand, to furnish the Assessor with a list of the property of the company of which he was superintendent, and that the company is estopped from questioning the sufficiency of the description so furnished in an action to collect the tax.

Hydraulic Nozzles.

A complaint has been filed by Joshua Hendy against Frank H. Fisher, alleging that on the 7th of May, 1880, the defendant conveyed to him an individual half interest in a patent hydraulic nozzle well known in California, he agreeing to furnish money to prosecute in the United States Circuit Court for infringement of said patent and to furnish money to prosecute persons to recover royalty for infringement of the patent for their joint account. Fisher granted to him the exclusive privilege of the manufacturing and sale of these patent machines, the profits to be equally divided between them. He brought suit in the United States Circuit Court in the name of Frank H. Fisher against Richard Haskin, J. H. Haskin, Joseph Craig and R. R. Craig for infringing said patent, and on the 4th of September, 1882, the Court adjudged that the defendants had infringed upon the patent, and that the complainant was entitled to an accounting of profits. An accounting was thereupon had, and the infringement amounted to \$16,465.33. On March 7, 1884, a final judgment was entered in the case in favor of Fisher and against Haskin et al. for the amount named. Upon this award \$1000 only has been paid. Since then a large number of persons and corporations throughout this State have infringed upon the patent and a large amount of royalties have been collected by Fisher and appropriated to his own use. It is alleged that Fisher is insolvent, but that he is still engaged in collecting royalties for infringements of the patent. The prayer of the complaint is that Fisher "be compelled to make discovery of all royalties collected by him;" that he account for the same and that he give the name and residence of those from whom he collected; that he be restrained from collecting such royalties or the judgment against Haskin; that a receiver be appointed to collect said judgment and all royalties which may be due, and to prosecute such actions as are necessary to make such collections.

ANOTHER announcement is made that the Providence mine, Grass Valley, has been sold,

ENGINEERING NOTES.

The Cable Road Principle Applied to Navigation.

Wm. McCormick of Astoria, has devised a plan to navigate the narrows of the Dalles, which is described by the *Astorian* as follows: Between the head of the Cascade and the foot of these narrows there are fifty miles of navigable river. The narrows average about 250 feet in width and are 8400 feet long, with a fall of seventeen feet in that distance; the walls are vertical, of basaltic rock, ranging in height from thirty to eighty feet, the water is very deep, and the bottom is presumably of such a nature as to prevent the use of a submerged cable. He proposes to build what he calls a floating towpath, which is a long, narrow raft or boom of logs, built in sections of fifty feet each. Each section is composed of eight logs; four bolted firmly together to form each side, being then framed together with square timbers, the whole forming a raft twelve feet wide, upon the upstream end of which are two pulleys, one above the other, revolving in a longitudinal direction, the purpose of which is to carry an endless wire rope. The sections will be coupled together with boom chains, there being one chain for every log in the outfit. The wire rope will have a set of pulleys supporting it at intervals of fifty feet for the whole distance, which is 10,000 feet from the foot of the narrows, to a point 1600 feet above the head. The power is to be furnished by steam at a point on shore. The manner of adjusting the slack, and thereby the tension of the rope on the engine drum, as well as that of getting the boat's tow-line past the pulley is difficult to describe without drawings. It appears that the arrangement is similar to the cable roads of San Francisco, and if it comes up to his expectations it will be a success, as it will enable boats, especially barges, to pass the narrows with nearly as much speed as they will make in ordinary water, while the boom serves to fend them off from the shore, thus avoiding the building of a canal and seventeen feet lockage. The scheme will cost about \$70,000, and is supplementary to his plans of a rapids tugboat at the Cascades. The two together would, if practically successful, open the river from Astoria to the foot of Tumwater Falls, which is the upper one of the Dalles series of rapids, a distance of 210 miles, and leaves but one short portage between the grain fields and deep water.

COMPOUND LOCOMOTIVE ENGINES.—A hot discussion of the merits and demerits of compound locomotives is now going on in *Engineering*, the last number containing five letters on the subject, only two of which are in their favor. The most important of the latter urges chiefly that, of the four chief classes of steam-engines, marine engines are now all but universally compound; portable engines and stationary are more and more built compound, and "why then should not the compound be equally successful when applied to locomotives, when it has the additional advantage of dispensing with coupling-rods?" The surprising information given in the same letter, that experiments on the Eastern railroad of France show a frictional loss of 35 per cent of the indicated horse-power "with four-coupled engines" should be taken with a good many grains of salt.

Another letter suggests, in favor of the new type, that it is a great deal easier to write on the cars behind them, the piston pulsations being less noticeable; but those on the other side take the more definite ground that they do not handle trains well, owing to difficulty in starting, are not liked by the men, and do not burn as little fuel as has been claimed, either absolutely or comparatively, when all proper allowances are made. All of which tend simply to show that the expediency of compounding locomotives, and especially of any specific plans for doing so yet in use, cannot yet be regarded as proven, although the steady increase of attention to the subject in several different countries shows that many experienced engineers have found reason to hope much from it.—*Railroad Gazette*.

SAND BAGS FOR ENGINEERING PURPOSES.—During the war of the rebellion sand bags were used for the foundations of fortifications on soft ground, notably during the siege of Charleston, where bags of sand were dumped on a mud bank forming an artificial island, upon which a fortification of sand bags and cotton bales was built of sufficient resistance to carry 15 inch "swamp angels," which were used to shell the city some seven miles distant. It has been supposed that all possible points were occupied, and until the use of sand bags was devised, it would have been impossible to erect a fortification upon such materials. In concrete work, such as the strengthening of the foundations of the Washington monument, it is sometimes advisable to apply the materials in bags, and afterward burst them by blows of rammers. A few years ago an inlet of about one-sixth of a mile in width on the eastern coast of New Jersey, was closed by an embankment made out of 80,000 bags of sand. The cost was one dollar per cubic yard of embankment. The deposit by the sea began as soon as the current in the channel was stopped, and now 100 acres of land have been reclaimed. This shore is sandy, and the great action of the waves and currents serves to wear or build the land very rapidly.

USEFUL INFORMATION.

WHAT TINFOIL IS.—It may not be generally known that tinfoil, as now so widely known to the trade, is not a foil of tin alone, but composed mainly of lead, with but a slight alloy of tin. The manifold appliances of tin foil to articles of consumption and medicine is not regulated with any law such as exists in European countries, forbidding the use of lead or composition, or otherwise impure tinfoil, in all cases where it may, through oxidation or contact with the goods, become poisonous and injurious to the health of the consumer. Too little attention has been paid to this subject thus far. It is too he hoped that ignorance, and not willful oversight of the facts, has led many manufacturers and dealers to use an article accompanied with such risks for the sake of saving a trifle in the cost. Besides, this saving is in most instances imaginary, as the German pure tinfoil combines such a fineness and a large yield with relatively great softness and strength, that it will practically answer most purposes, and not cost more than an equal surface of the lightest composition foil, while the heavier grades of the latter will be much more expensive to use. The yield of the regular German tinfoil is seventy-two square feet, or 10,368 square inches per pound; a heavier grade yields sixty-six square feet. The sheets are of large size, and waste in cutting is consequently small.

ENGRAVING ON GLASS.—The hard point for inscribing and engraving rare stones is doubtless older than the lathe, and was certainly used in engraving glass during classical and mediæval times. The Flemish, Dutch and Germans, within the last three centuries, used it with great success, as testified by examples of their work still remaining. Diamond or other hard stone point—or steel points similar to those used by some glass carvers of the present day—may be employed in engraving glass, and handled in the same way as ordinary gravers for metal or wood. The glass should be coated with a mixture of gum and milk, on which, when dry, a pattern may be drawn or transferred previous to engraving. Very fine line and hatching and stipple effects can be produced by this method. Some of the specimens in the Slade collection of the British museum are exquisitely done, especially those attributed to Wolfe and Heemskerk. The great drawback to such engraving, when delicately finished, is that it cannot be well seen unless it is held close to the eye and in a good light.—*Art Journal*.

A NEW BUOYANT FABRIC.—An experiment which should be highly interesting to the public at large took place in the Thames at Westminster recently. Several persons, including a lady, a clergyman, and military and naval officers, all clad in the garments which were apparently those in common use, embarked in a small boat, and on arriving in midstream proceeded to jump into the water. They appeared to be perfectly at their ease, and, making no movement, rested calmly with their heads appearing above the surface. The explanation of the phenomenon was that the clothes worn by these people were made of a fabric in which fine threads of cork were interwoven with other material. Mr. Jackson, the inventor, is to be congratulated on the complete success of the ingenious device, which is a vast improvement on the unwieldy Boyton dress. The *Pall Mall Gazette* thinks that timid sea travelers can now equip themselves in garments which, while being undistinguishable from those of ordinary mortals, will make death by drowning an impossibility.

MICROSCOPIC MOUNTINGS.—Henry Dalton, the late eminent English microscopist, used to make on glass, from the scales and hair of Brazilian butterflies, the representation of a bouquet, which, seen through a powerful instrument, showed eighty-two distinct flowers of various shades and colors. To the naked eye the bouquet looked like a small shot. There are not more than fifty Dalton slides in this country, and they can scarcely be purchased for love or money. Gray's Elegy, containing thirty-two verses, has been photographed by the aid of a microscope on a slide within a space of one-tenth of an inch square, and is perfectly legible when read through a powerful instrument.

OIL ADULTERATIONS.—Adulterations of animal oil or mineral oil may be detected by adding sulphuric acid, when, if animal oil is present, that portion will be charred, forming black rings in the sample being tested. Vegetable or animal oils can also be detected by adding an alkali to the sample, thus causing them to saponify immediately, as mineral oils have not the property of saponification very readily. Oils are frequently adulterated with cotton-seed oil, which is very dangerous, from its tendency to ignite waste spontaneously. Spontaneous ignition from oil must generally arise from each adulteration, which should be carefully guarded against.

THE PRESERVATION OF COPPER SHEATHING.—M. Carnot reports, on behalf of the committee on chemical arts, that a small quantity of metallic manganese, as an alloy containing 75 per cent of copper and 25 per cent of manganese, prevents the formation of cuprous oxide, which

is the cause of the formation of soluble salts, which accelerate the corrosion of sheet copper employed for the sheathing of ships. By this method, the durability of copper exposed to the action of sea water is greatly increased.

RESTORING PLUSH.—It is customary to use ammonia for the purpose of neutralizing acids that have accidentally or otherwise destroyed the color of fabrics. This must be applied immediately or the color is usually imperfectly restored. After careful use an application of chloroform will bring out the colors as bright as ever. Plush goods and all articles dyed with aniline colors, faded from exposure to light, will look as bright as ever after sponging with chloroform. The commercial chloroform will answer the purposes very well. This information will be found very useful, as chloroform, which is quite cheap, readily restores the color of faded plush garments that have been consigned.

TO CLEAN KID GLOVES.—Stains may be removed even from the most delicately colored kid gloves without injury by suspending them for a day in an atmosphere of ammonia. Provide a tall glass cylinder, in the bottom of which place strong aqua ammonia. Be careful to remove from the sides of the jars any ammonia that may be splattered upon them. Suspend the gloves to the stopper in the jar. They must not come in contact with the liquid.

INSOLUBLE GLUE.—In order to render glue insoluble in water, even in hot water, it is only necessary, when dissolving it for use, to add a little potassium bicromate to the water and expose the glued part to the light. The proportion of bicromate will vary with circumstances, but for most purposes it will be necessary to add only about one-fiftieth of the amount of glue present.

CEMENT FOR PLASTER CASTS, ETC.—To repair broken articles in plaster, a good cement may be prepared as follows: Dissolve small pieces of celluloid in ether. Decant the liquid after a short while. The pasty residue is a cement that will dry rapidly and not dissolve in water if the articles should be exposed to it.

EXPERIMENTS conducted by the Dutch State railroad, on the behavior of different paints on iron work, have shown that red lead best resists the action of the atmosphere. It was discovered, too, that the coat holds better on iron plates cleaned by pickling than when the plates have been scraped or brushed.

MINCE MEAT is now put up dry, in sealed packages. It is said to be of superior quality, and will keep any length of time, winter or summer, in any climate, and especially and peculiarly adapted for spring and summer use; no risk in spoiling in warm weather; always ready and handy for use.

EXTREME COLD ON TIN.—Extreme cold converts tin into a semi-crystalline mass containing large cavities. The pipes of a church organ have been so altered by cold as to be no longer sonorous.

GOOD MEALTH.

My Boy, Do You Smoke?

Among civilized nations the use of tobacco is strictly a modern vice, unknown 250 years ago. Its antiquity among the American Indians can only be conjectured. Smoking is now very generally admitted to be a serious detriment to health, especially when the practice is taken up at an early age. It is strictly forbidden in the German army—or at least it is not allowed under a certain age.

The United States Navy annually takes into its service a large number of apprentice boys, who are sent all over the world and taught to be thorough sailors. It has been the policy of the government since the war to educate the "blue jacket," upon the principal that the more intelligent a man is, the better sailor he is likely to become. There is no lack of candidates for these positions. Hundreds of boys apply, but many are rejected because they cannot pass the physical examination. Major Houston, one of the Marine Corps, who is in charge of the Washington Navy Yard barracks, is the authority for the statement that one-fifth of all the boys examined are rejected on account of heart disease.

His first question to a boy who desires to enlist is: "Do you smoke?" The invariable response is, "No, sir," but the tell-tale discoloration of the fingers at once shows the truth. The surgeons say that cigarette smoking by boys produces heart disease, and that in 99 cases out of 100 the rejection of would-be apprentices on account of this defect comes from excessive use of the milder form of the weed. This is a remarkable statement, coming, as it does, from so high an authority and based upon the results of actual examinations going on day after day, and month after month. It should be a warning to parents that the deadly cigarette is sure to bring about incalculable injury to the young. A law passed restricting its use to the duds would not, perhaps, bring popular disfavor, because it might reduce the number of these objects about our streets, but boys indulging in the cigarette ought to be treated to liberal

doses of "rod in pickle" until the habit is thoroughly eradicated.

THE COCA LEAF is said to be an excellent stimulant for the nervous system when chewed. It is of the nature of opium, but less violent and more lasting in its action. Bernays says: "There is so much concurrent testimony as to place beyond doubt the fact that the moderate use of coca leaves as a masticatory enables fatigue to be endured with less distress and with less nourishment. Markham says that he chewed coca very frequently, and, besides the agreeable, soothing feeling produced, he found that he could endure long abstinence from food with less inconvenience than he would otherwise have felt; and it enabled him to ascend precipitous mountain sides with a feeling of lightness and elasticity and without losing breath. To the Peruvian Indian coca is a solace which affords enjoyment and has a most beneficial effect." Quoting from the same authority: "The incredible fatigue, says Von Tschudi, endured by the Peruvian infantry, with very spare diet, but with the regular use of coca, and the laborious toils of the Indian miner kept up under similar circumstances throughout a long series of years, certainly afford sufficient ground for attributing to the coca leaves not a quality of mere temporary stimulus, but a powerful nutritive principle." The average Peruvian Indian chews a very large quantity of coca leaves every day. Good authorities place the amount of cocaine daily absorbed by such of these people as chew to excess at from 30 to 40 centigrams. The excessive use of coca is well known to be injurious, and the unsteady gait, the yellow colored skin, the dim, sunken eyes, the quivering lips and general apathy are the indications of the inveterate coca chewer. It is, however, considered the least injurious of all narcotics in use, and in the higher regions of the Andes its effects are less marked than in warmer and damper districts. As a palliative agent in the hands of a skillful physician cocaine is capable of greatly alleviating human suffering.

ANCIENT HYDROPATHY.—Hydrotherapy is not a modern invention. It was at Rome in the reign of Augustus, that hydropathic practice had its birth under the happy inspiration of a freedman—Antonius Musa. This physician prescribed water as a drink, in baths and in douches, and he found in this remedy, simple as it was, the secret of a new system of therapeutics. Augustus had only just been elected consul for the eleventh time, when he fell ill with a dangerous sickness. Feeling his end approaching, he assembled the magistrates, the senators and the principal knights, and then, having conferred with them on the affairs of the republic, he placed the seal of the empire in the hands of Agrippa. It was then that Antonius Musa undertook to cure him by a new method, and succeeded by means of cold water applied both internally and externally. Full of gratitude, Augustus bestowed on Musa a large sum of money and a gold ring, and had a statue raised to him, and placed beside that of Esculapius; also conceding to him and to whoever then exercised, and hereafter should exercise the same profession, nobility and the exemption from payment of taxes. Musa was not long in gaining a universal reputation. "Ah, Musa," cried Virgil, "no one may flatter himself that he will ever surpass thee in science!" Hydrotherapy was already superseding every other branch of therapeutics. Horace, himself, had recourse to this famous physician, and the poet, after having sung the praises of Falernian, sought the virtues of cold water. Horace set out for Velia, where Musa prescribed for him a hydropathic treatment, and afterwards took the sulphur baths at Baie. But for the loss of a distinguished patient, this mode of treatment would have become general. The death of young Marcellus ruined for a time the system and its founder.

IMAGINATION AND DYING.—In reference to the influence of the imagination on the body a doctor tells the following story in the *Chicago Times*: "A big hulking fellow about 10 miles from the town I was practicing in got the idea that he was going to die at just 11 o'clock in the forenoon of a certain day. About 9 o'clock a messenger came for me. I hurried out. When I got there the crank had 15 minutes to live, according to his calculations. He did look like a man on the verge of eternity. His eyes were dim and sunken, his face had that peculiar pallor which heralds the near approach of death, and his breathing was very labored. The family were gathered around and weeping as they took a final leave. Something had to be done quick. There was a smart-looking woman there, and I called her aside. Pointing to the clock on the mantel-piece, which the patient was watching, I said: 'When I have his attention turn that ahead.' Then I crowded into the family group, hustled them into next room, sat down on the edge of the bed and began telling that fellow one of the most horrible murder stories you ever heard. I located it right in the town where he knew everybody, named the woman killed, went into blood curdling details, and so completely interested the man that he forgot his 11 o'clock appointment. When I gave him a chance to look again it was 20 minutes to 12, and he was actually mad for a time, claiming he had been tricked. He finally got to laughing and we all took dinner together. The next day he whipped two men at a barn-raising for twitting him about the programme of death that miscarried."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

KENNEDY.—*Ledger*, Nov. 20: The water power to be used for boisterous purposes is expected to be ready to be placed in position in a few days. The intention is to operate through the main or south shaft. Men have been at work renewing the wood-work wherever necessary, and placing the works in good condition. The shaft is 800 feet deep; it will be drained by means of a bucket holding 500 gallons. There are three levels, and the work of freeing the mine of water will take considerable time. When work was suspended, the ore in the bottom of the mine averaged about \$6 per ton. There were no facilities for saving sulphurets, and the mill was not equal to crushing more than half a ton to the stamp per day. Under those circumstances it could not be made to pay. But with proper machinery there is little doubt that the property can be put on a paying basis. The Mammoth mill has resumed operations, running during daytime only.

Calaveras.

SOLD THEIR INTERESTS.—*Calaveras Chronicle*, Nov. 21: Edward Fahey and Andrew McFadden, who owned a quarter interest each in the What Cheer mine, sold their interests to the Oakland company who have been opening and prospecting the mine, for \$1000 each. The company had a short time since bought out the interests of M. Boughton and A. F. Newton for \$750 each. The company has been to considerable expense in putting up machinery and opening the mine, but the developments were sufficiently encouraging for the company to consummate the purchase of the entire mine from the former owners.

MACHINERY.—More machinery for the Nevill mine at Angels, passed through town Tuesday last. The first load of castings that passed through here for the same place reached their destination with numerous hardships in the transportation on account of the bad condition of the roads.

Marin.

THE KIMBALL RANCH MINE.—*Marin Co. Journal*, Nov. 20: The new mine on the Kimball ranch keeps up its grand promise. Mr. Rose placed a 6-stamp mill in position last week, but found that the engine that he took out from San Rafael was too small to run it. He managed to run through two or three shovels of soft rock and dirt and from this he took a ball of silver worth about \$5. The promise from this sample is about \$4000 per ton. Mining men who visit the place say it is one of the richest deposits ever discovered anywhere. There is no stock and no interest for sale. The owners are sanguine that they have a bonanza and would scout the idea of selling any part of it.

Mariposa.

THE FRANCIS MINE.—*Herald*, Nov. 20: The Francis mine and mill are running night and day, with good results. The rain will supply plenty of water, a commodity that has been quite scarce there for the past two months, and the mill will be run to its fullest capacity in the future. The raise from tunnel No. 2 to the tunnel above has been completed, supplying plenty of fresh air, and good rock is taken from tunnel No. 1. A chute connects the two tunnels, and cars are run to the mouth of tunnel No. 2, from which the ore is carried in a chute to the mill. Messrs. de Bourdage and Chodzko are well pleased with the prospect for a paying property.

Napa.

NAPA SILVER MINE.—*Calistogan*, Nov. 20: Friday last we visited Johnson & Grigsby's silver mine. The quantity of ore raised to the surface has been greatly increased, the dump being much larger than it was a few months ago. Work is being prosecuted on the three levels of the mine now, though the number of men employed in and about the property is about the same as heretofore. Very rich ore is being brought to the surface daily, and is obtained only in the work of drifting, as there has not yet been any stoping done. The owners of the mine will not, this winter, construct the proposed dam in the Coltrin Canyon, nor erect a mill the present season, this work having been deferred till next year—perhaps the coming spring. On account of the comparatively slow progress made in developing the mine, people are occasionally inclined to believe that it is of little value, but, on the contrary, it is a magnificent piece of mining property. This will be made apparent when everything is finally ready for business; and then there will be displayed as fine specimens of engineer's work and as perfectly equipped mill and mining property as can be found in California.

Nevada.

PEABODY MINE FILLED WITH WATER.—*Tidings*, Nov. 18: A small disaster has occurred at the Peabody mine, caused by the storm. The shaft is close to the bed of Rhode Island Ravine, which rages sometimes when the rains are roaring. Last night, or this morning, a hole broke through the bottom of the ditch into the mine and that let the water of the ditch and of Rhode Island Ravine into the excavation below. There was one man in the mine at the time and he got out with difficulty. Of course the mine soon filled up, and tools, pump and other property are in there under the water. There will be no great difficulty in pumping out the mine; only a few days work.

MINES IN EUREKA TOWNSHIP.—George Mainhart, one of Nevada county's best miners, has just returned from a tour of inspecting mines in Eureka township, in the vicinity of the town of Eureka. Mr. Mainhart went in the interest of some Sacramento parties, who will do some extensive work up there next year. Mr. Mainhart says that the California mine (quartz), near Eureka, has just been sold, to San Francisco parties, for something in the neighborhood of \$20,000. The California was owned by Bohanan and partners, and has very promising prospects for its future as a gold producer. It

is the intention of Mr. Mainhart to get into the Eureka district as soon as the winter is over.

EUREKA MINE LEASED.—*Tidings*, Nov. 18: Elisha and Thomas Andrews have leased the old Eureka mine, for an indefinite period, from Robert F. Morrow, who acts for the company owning the mine. The Messrs. Andrews have purchased an 8-stamp mill from Weissbein Bros., and will erect the mill on a site opposite the water wheel of Bush & Gauthier. This mill is to be run by water power supplied from Stone's ditch. A Pelton wheel will be put in, and all modern improvements will be used in the mill. The fall of water at the wheel will be about 80 feet, which will be sufficient to run more stamps, should the lessees see fit to erect them. Work of crushing will at first be commenced on the old dump of the Eureka, and when the best of the sorted rock from that large pile shall have been exhausted, then ore will be crushed from the mine. A party of miners will go to work in the old Mobile tunnel (the Richardson ground), and will take out ore on shares from the ledge in the tunnel until they have reached the Eureka ground. The Mobile tunnel starts in the hill west of the Eureka old works and runs in about 250 feet in a direction north of west. The miners think they can strike the glorious old Eureka ledge in a little way through this tunnel, and if they succeed, Grass Valley can lay claim to another bonanza in her already rich quartz developments. The mill to be erected will be placed on Powning & Co's, patented ground, and besides being used for the Eureka work, will also crush custom rock when circumstances allow.

Placer.

IRON SMELTING.—*Republican*, Nov. 20: January 2d is the day set for beginning work at the Hotelling iron furnace, and at that time 40 or 50 men will be added to the force of about 30 working there at present. Shaft No. 2 has recently been sunk 126 feet, making the total depth 192 feet, and a large quantity of good ore has been found. Drifting is about to be begun. William Greerhauser, the superintendent of the furnace, leaves to-day for the East. He will be gone about a month and will bring back with him three or four men skilled in various kinds of work connected with the mine and smelting furnace.

Shasta.

GRAVEL.—*Republican Free Press*, Nov. 21: Mr. Garber, of Portuguese Flat, who was in Redding Tuesday evening, thinks that from appearances his company will have a good run this winter on their gravel claim. For the past two seasons little has been done through scarcity of water. Their ground prospects very rich, and will doubtless pay well under favorable circumstances.

SHUT DOWN.—J. O. Stewart, of Copper City, was in town last week and reported that the mine had shut down on account of the wet weather, the mine at present being in such a condition that ore cannot be extracted when it storms. At the mill they have been furnishing employment to some 20 men, who are temporarily laid off. Mr. Stewart says that they have shipped some \$10,000 in bullion since starting up, and that the process works well. He thinks that by reducing the expense of handling the ore to the lowest figure that a profit can be made.

NOTES.—*Shasta Democrat*, Oct. 21: A new pump for the Clark mine at Quartz Hill was taken to the mine yesterday. McCusick, ex-Postal agent, returned here Monday evening on a visit to the mines. We are told that fully 150 men are employed by the Iron Mountain mining company.

Sierra.

PIKE CITY.—North San Juan Times, Nov. 20: We made Pike City a visit on Thursday. The hands at work in the Alaska had just been paid off, and many of them were enjoying a holiday. We found the Alaska mine working full-handed, though the new stamps were not running. The mine is now working to its full capacity. When the additional twenty stamps are set going its gold producing capacity will be doubled. The Alaska is certainly the best mine within a radius of fifty miles of that place. The town of Pike City is increasing in population daily, and if the Alaska remains as good a paying institution as at the present, the town in another year will contain treble its present population.

THE FUTURE OUTLOOK.—*Sierra Tribune*, Nov. 23: The success of the Young America claim has given a great stimulus to prospecting for mines in this district. During the last few months many discoveries have been made that give promise of turning out well. By next summer we believe that Sierra City will be the center of greater mining activity than exists anywhere else on the Pacific Coast. On all sides the work of prospecting is pushed vigorously, and discoveries that promise well are frequent.

PAY GRIT.—A private letter received at this office states that our old friend, B. F. Littlejohn, has struck a 3½ foot gold-bearing ledge in his claim at Middle Waters, and that the vein appears to increase in richness as depth is acquired. The rock also carries large quantities of sulphurets. The finder thinks he has a pretty good thing, and as soon as spring opens he will endeavor to put up some kind of a crushing apparatus.

A BIG CLEANUP.—We are informed that \$1600 was cleaned up for the last 10 days' run at the Belmont Consolidated quartz mine, Poker Flat. That is pretty good, considering the milling facilities they have. The Belmont is a valuable mine.

LET A CONTRACT.—The Lewis Consolidated Mining Company has let a contract to parties to run 100 feet of tunnel at their claim. They have also laid in supplies at the mine, and otherwise prepared for doing a good winter's work.

LIVELY TIMES.—We confidently predict for this district, the coming summer, lively times. Capitalists are getting their eyes opened to the merits of our mineral resources.

THE CLEVELAND MINE.—The Cleveland is now ranked as one of the most promising mining properties in this district. The lower tunnel is in about 300 feet, and the ledge, which was encountered there several days ago, is said to show 2½ feet in width of as fine looking quartz as can be found anywhere. The striking of the vein in the lower adit, at a depth of 250 feet from the surface, determines that the mine is a valuable one beyond a peradventure of doubt. The eight-stamp mill is completed, and if it has not

already started up, will within a day or so. Parties who ought to be good judges of such things, have placed the milling value of the ore at from \$40 to \$50 per ton. If it pays one-half that the owners will grow rich very fast, as the mine, being worked entirely through tunnels and the mill run by water power, the expense of extracting the ore and getting out the gold therefrom will be but nominal. Antone Demartine has exhibited a great deal of energy and pluck in pushing ahead the developments on the property.

CLEANUP.—*Mt. Messenger*, Nov. 20: The Ruby Co. cleaned up for last week 106½ ounces. There are 33 men working. Supt. Colman has crossed the channel, raised 25 feet and found gravel on a bench, 7 carloads of which yielded \$2 per carload. It was pay day at the Extension last week, and \$4,675.75 was distributed among the miners. There were 72 names on the pay roll last month.

THOS. HENRY and Abe Lightall are running a tunnel on the Fairchild quartz ledge near the head of Kanaka creek. Henry Raymond is sinking a shaft on his quartz ledge, already down a considerable depth.

SIERRA CITY.—*Cor. Mt. Messenger*, Nov. 20: The outlook of the place is most encouraging at the present time—a great deal more so than at any time in the past. Young America, has already paid some dividends. This mine is some distance from the city. Young America is a good mine, and one which will last for years, from the amount of ore at present in sight. The extension to the Young America is not prospected much as yet. The Phoenix, has a very fine location and every natural advantage to work it on an economical plan. It is rumored that the mine has changed hands or will in a short time. A San Francisco company is the prospective purchaser. The Kentucky is a good property, with every advantage that a company could wish for, having the same water privileges and advantages as the Phoenix. The Marguerite was discovered by A. C. Busch & Co., and was sold to the present company, which has been working it about three years. No work has been done during the past year owing to some trouble with the company. The mine has very rich rock. The mines I have spoken of are all high grade rock, and with a little capital all could be made big dividend paying mines, and no better locations and advantages can be found in the State of California. There are a great many other ledges within a few miles of the city, which have not been prospected to any extent.

Siskiyou.

PICK AND PAN.—*Yreka Union*, Nov. 20: All is activity in the Salmon mines and the indications are favorable for a long and profitable run. The rich placer mines around Hawkinsville are being worked to good advantage, the big ditch furnishing an abundance of water since the late rains. The Oro Fino hydraulic miners have commenced work and look forward to a long season. The extreme richness of the mines about Oro Fino make even short runs quite profitable. During the dry season many tons of quartz were taken out, and the mills and anartras in that section will be started at once. The profits of William McConnell's Klamath river claim were not as large this year as last, but the enterprising owner has no cause to complain. He worked at a great disadvantage from the first, having encountered a large body of sand, and at no time during the season was bedrock reached. At the commencement of the season he employed 45 hands, but finding it necessary to abandon one derrick, the force was reduced nearly one-half. The running expenses this year were about \$15,000 against \$20,000 last year, when he cleared \$9000 on the season's work. Next spring he will open the claim lower down which will enable him to work richer gravel than he has yet handled.

Trinity.

NEW RIVER.—*Journal*, Nov. 21: While at the New River mines this week we learned that about 75 men will winter there. The Hardtack, Ridgeway, Mountain Boomer, Grover, Cleveland, Modoc, Uncle Sam and other mines will continue developments during the winter and also crush ore. All have good rock and the district may be said to be fairly prosperous. We have much faith in its future, feeling certain that the first great rush being over the district will build up on its merits and prove one of the most prosperous quartz mining camps on the coast.

Tuolumne.

NEW MILL.—*Union Democrat*, Nov. 21: Messrs. Tullock and Ashlock returned Thursday from Sugar Pine, having completed the new mill on the Hogle & Dagner mine upon which they have been engaged for some time. The mill is now all ready to run, and will be started up as soon as the necessary belting is received. It is built with frames for three 5-stamp batteries, but as yet only one battery has been set up. It is intended to add the other batteries to the crushing capacity of the mill whenever the ore output justifies it. The motive power of the mill is steam. Crushing will probably be commenced now in a very few days. The pocket miners on Bald Mountain still continue to strike pockets. Last week was quite golden, a number of rich pockets were taken out by different parties. Al. Harkness, we are to hear got his first in the sugar again. There are several partially developed mines now lying idle on Bald Mountain with good prospects in sight which if worked would no doubt pay handsomely, but they require time and labor as the past has proven that this mountain of wealth will not yield its golden treasure without a faithful and industrious effort.

RIVER WORK.—*Tuolumne Independent*, Nov. 20: Mr. J. R. Moffit informs us that he is well satisfied with his season's work in the river near Jacksonville. Although he "did not get all the gold he wanted," his experience with his new mode of river mining has convinced him of its value and importance to the mining interests of the State. By means of his new and novel construction of movable dams, he got them out quickly and safely when the floods came, as also all his other apparatus which is likewise constructed with a view of quick removal in emergency. By this new plan of movable dams he is also able to get into the river bed earlier in the season, and to stay until the last moment in the fall. This year he had but 200 feet of rubber hose to convey water from the dam across his mine, but next season he will have 800 feet. This hose (his own

invention) is four feet in diameter, and carries an immense body of water. For pumping he uses a new style of turbine wheel (also his own invention); fitted with cogs it has positive action; it threw an 80-inch continuous stream with a force that sent the water four feet from the outlet. Its capacity is only a question of power. In the river bed he encountered large boulders, some of them ten feet through. He gets rid of these by putting several sticks of giant powder in a bag, the middle one with fuse. The bag is let down in the water, close to the rock, and the charge exploded. By this means these immense masses were knocked into splinters. No expensive drilling was needed to get rid of them. The charge must be close against the rock, as otherwise the water between the boulder and the bag would act as a cushion, and render the blast of no effect. Being now fully prepared, and with much additional experience, he will be able to get into the river bed and to work next season much sooner. He has other improvements and new plans for working river beds, which will develop this great mining industry, and render it profitable in places where, heretofore, it has been too expensive for profit.

GOLD.—During the past two weeks, Al. Harkness, on the Garrett claim, at Brown's Flat, has taken out about seven thousand dollars. In one day the pocket yielded seventy-two ounces. In a little over a year, different parties, to whom the claim has been leased by Mr. Garrett, have taken out over \$50,000—the true figures are probably nearer \$60,000.

NEVADA.

Washoe District.

CHOLLAR.—*Enterprise*, Nov. 21: The main lateral drift south on the 3100 level is now in 412 feet from the switch at the west drift from the Combination shaft. This south lateral drift of the Chollar may well be termed the "lightning drift" of the lower levels, for the regular weekly rate of progress is about 83 feet—faster work than has yet been done at that depth on the Comstock. It is being run in the black dyke formation, composing the west or foot wall of the ore vein; the ground works very favorably; no water is met with, the air is good, and the men can work to excellent advantage. The proposition is to run it through to the Potosi north line, 200 feet distant, which will take about three weeks. Then, if deemed expedient, through that mine, 700 feet further, to the Bullion north line. In case this is done, the Bullion company propose sinking the Ward shaft 700 feet deeper, and drift north from it to connect with this lateral drift coming from the Chollar on the 3100 level. This would make a very advantageous connection for air circulation and exploration purposes, and a drift south from the Ward or Bullion shaft could connect through to the Yellow Jacket shaft with good facility. During the past week an important reduction of inflowing water has been made on the 2100 level. Some years ago, in running the lateral drift on this level, to connect with the Savage incline, two long dirt holes were bored from the face which did not hit the incline, but to the westward of it. Two fine streams of water were tapped, however, which have flowed strongly ever since. The drift subsequently connected with the incline, which was found to lie further east. A few days ago the underground foreman suggested to Superintendent Hamilton the possibility of stoping out that water, and acting upon that proposition two long wooden plugs were driven those two holes. This had the effect to effectually shut out an objectionable inflow of nearly 100,000 gallons of water per day, making quite a perceptible difference in the work given for the big hydraulic pump to do.

HALE & NORCROSS.—On the 3100 level the main lateral drift is being steadily advanced, following along the easterly skirting of the ore vein, which lies entirely to the west. The face is in a mixture of good ore and vein matter, and porphyry and clay, with no water, and is now in 110 feet north of the deep winze station. In another week this drift will be advanced to an equal extent north with the main lateral drift on the level above—the 3000—and both will be about 100 feet from the Savage south line. On the 3000 level the crosscut west, about 50 feet south from the face of the north lateral drift is again being advanced, in order to get room to put a diamond drill into its face. The drill will be followed up by the crosscut, the main purpose being to reach and explore the point where the continuation of the good ore body met with on the 2900 level should be found. On both lower levels, 3000 and 3100, the water is getting pretty well drained out, and gives very little trouble.

CON. CALIFORNIA & VIRGINIA.—On the 1750 level the ore breasts are showing and yielding well, the daily extraction being about 125 tons, giving an average assay of \$19 per ton. On the 1650 level the main northwest drift is again being pushed ahead, going after the old stopes of low-grade ore—bonanza leavings. It is in nearly 200 feet. From the Jones lease section, above the 1500 level, about 100 tons per day are extracted. This ore is shipped to the Eureka mill, on the Carson river, for reduction, and assays about \$16 per ton.

YELLOW JACKET.—The Brunswick mill having dispensed with its auxiliary steam power and being run entirely by water, does the same amount of work as heretofore, and the regular yield of the mine, about 175 tons per day, is continued. The lateral drifts north from the 1200 level of the Crown Point to explore and prospect the mine at that depth is making good progress, notwithstanding the great heat, and is penetrating the north portion of the mine, where good ore is expected to be met with.

CROWN POINT.—Nearly 500 tons per day are now being extracted from this and the Belcher mine. Most of it comes from the upper levels of Crown Point. That from the Belcher is principally from the 1700 level. During the last week or two several tons per day have been contributed from the 1200 and 1750 levels of Crown Point, which is of higher grade than that from the upper workings.

OPHIR.—On the 400 level the lateral drift south from the main west drift is now in a little over 200 feet, still following the excellent and promising vein formation in which it was started. Good little bunches and streaks of ore are occasionally met with, and a good concentration of the same is liable to be met with at any time.

BEST & BELCHER.—On the 1000 level the cross-cut west was extended 52 feet, making a total length of 142 feet. Some good quartz and clay are met with; also, a little water.

MEXICAN.—On the 500 level the middle crosscut east has been discontinued, and two lateral drifts north and south started from it at a point 200 feet east of the main lateral drift. They are intended to explore a highly-mineralized portion of the vein, passed through at that point. They are each in about 50 or 60 feet.

GOULD & CURRY.—On the 1000 level west cross-cut No. 1 has been suspended, and No. 2 started about 170 feet south of the north line, or opposite the shaft. This new crosscut is now in 100 feet, having made 60 feet during the week. Material in face hard, dry vein matter.

ALTA.—The west drift on the 700 level has connected with the upraise from the 950 level, giving a fine air circulation and increased facilities for explorations on the 700, where good streaks are found among the great mass of low-grade ore.

SIERRA NEVADA.—The lateral drift north on the 520 level was advanced 37 feet during the week, making a total distance of 273 feet. The water has decreased, and the vein material met with is found to be harder with further advancement.

KENTUCK.—The old ore breasts above the 1300 level are giving a considerably increased yield, over 100 tons a day, or sufficient to keep the Rock Point mill steadily running and also, the Douglass mill in lower Gold Hill.

UNION CONSOLIDATED.—On the 500 level the east crosscut, 100 feet south of the Sierra Nevada line, is still pushing ahead in promising vein matter, and is in about 245 feet.

Black Hawk District.

ANOTHER GOLD MINE.—Walker Lake Bulletin, Nov. 18: News came of a new mine in Black Hawk district, near Marietta. A gold bearing ledge has been found, which assays from \$41 as high as \$78 a ton. A shaft has been sunk thirty feet, which shows a ledge as far as developed. Taking it altogether, it is a very promising prospect. It is owned by Thomas Woodruff, Tom Purcell and Jack Doody.

Cherry Creek District.

MILL.—White Pine News, Nov. 21: Sometime this week the Ti-Cup mill will be started up on May Ann ore, and they expect to have a run of about two months. They are now taking out lots of fine ore. The furnaces at Jasper and Spacemont are running out some fine bullion, and parties from there say it will pay handsomely. If it does, look out for a boom there next spring.

Columbus District.

THE NEW MILL.—True Fissure, Nov. 20: All was stir and activity on the big west of town yesterday morning, when the teams began to arrive with the machinery for the new mill of the Candelaria Water and Milling Company, formerly known under the name of the Princess. Spectators outnumbered the workmen three to one, and the congratulations that passed between them were hearty. Contractor White put six men at work last Tuesday, but the severe storm of the past few days has kept them idle most of the time since. On Wednesday evening four carloads of machinery arrived, and the weather clearing up yesterday morning, the working force was increased to twelve. A lot of lumber and several more carloads of machinery are on the way. If nothing unexpected happens, the contractor hopes to have the 30 stamps ready to fall inside of 100 days. The resumption of work on this property is only one of the many signs of an approaching revival of business in this camp that will put it on a more solid basis than ever. A good time is in store for us.

BREAK OF DAY.—This mine is located in the White mountains, and is owned by David Davis & Co. There is a shaft down twenty-five feet on the ledge. It is intended to run a tunnel 150 feet in length to tap the ledge at a depth of 200 feet. There are about twenty-five or thirty tons of \$100 ore on the dump.

BOB INGERSOLL.—We are working two shifts. The tunnel is in 185 feet, thirty-five of which are in the ledge. The ledge can be traced for 27,000 feet, and good assays can be obtained for the whole distance. The mine is located in the White mountains, eleven miles from Fish Lake valley.

TIP-TOP.—The tunnel on this Santa Fe property is being pushed rapidly ahead in favorable ground, and is making a good showing.

CLIMAX.—Kent & Co. are making good headway in driving their tunnel. They expect to tap the ledge in a few days.

BALDWIN.—Work on the Baldwin, at Santa Fe, is progressing as usual.

AXAN.—Davey & Hastie are doing good work with encouraging returns. "Copper John" is still taking out the usual amount of copper from the Santa Fe mine. All the prospectors and chlorides in Columbus district are doing well.

Esmeralda District.

THE AURORA MINES.—Walker Lake Bulletin, Nov. 18: Mr. R. B. Mitchell, of San Francisco, the attorney for the Consolidated Esmeralda, (limited) of London, England, arrived in town on Monday. He is here for the purpose of passing the title to the large mining properties in Aurora, lately purchased by the London company. Work upon the properties will soon be commenced.

Hawthorne District.

CLOSE WORK.—Walker Lake Bulletin, Nov. 18: The tailings of the Kinkaid mill for the last four or five months have been tested at the Virginia assay office, and show no value. The ore averages \$15 per ton. This is in reality working it "for all it is worth." The mill is now running steadily and will soon commence crushing the rich rock recently discovered in the Montreal mine. Foreman McNeil feels confident that he can run as close on the rich rock as on the lower grade.

FROM THE LAPANTA.—Virginia Enterprise, Sep.

21: D. B. Lyman, Superintendent of the Sierra Nevada, Gould and Curry and Best and Belcher mines, returned evening before last from a visit to the famous Lapanta mine, Hawthorne District. He speaks of it as a rich and remarkable discovery. The ledge is from one to three or four feet in width, rich in free gold, with but little silver, with walls of limestone formation. The main shaft or incline is down about seventy feet, and from the dump at the surface he took a fair average quantity of the decomposed ore, which gives an assay of \$232.95 in gold and only \$2 in silver. From a piece of the hanging wall he got an assay of \$435. There are other smaller veins in the hillside of the same kind and quality of ore, one about 200 feet further down the hill being eight inches in width at the depth of thirty-five feet, although it showed only two or three inches at the surface. Lyman thinks there is at least \$100,000 in sight in the Lapanta, and looks for very rich results from further explorations.

Jackson District.

THE PENNSYLVANIA INCORPORATED.—Silver State, Nov. 20: The Pennsylvania Mining Company of Jackson District of this county has been incorporated in San Francisco. The capital stock is \$10,000,000, divided into 100,000 shares. The Directors are A. W. Sisson, George A. Scott, D. W. Earl, M. L. Cheney and John F. Caswell. A mill is now being erected on the mine, which is situated about thirty-seven miles a little north of west from Winnemucca.

Pahranaagat District.

WORK SUSPENDED.—Pioche Record, Nov. 18: Work has been temporarily suspended on the Bialbec mine, in Pahranaagat, until adequate milling facilities are procured. This is the mine that work has been vigorously pushed ahead in by Eugene Howell, who has opened it up in good shape, having uncovered an 8-foot ledge of good grade rock, in the drift running west from the bottom of the mine, and has just recently made a test of 34½ tons of the ore averaging \$86 and upwards per ton, and working it up, wet crushing, to 83 per cent and 87 per cent, shipping in bullion last month, as a result from the 34½ tons two bars valued at \$2542, showing a saving of over \$73 per ton. This is much more than was expected, as the ore was of decidedly rebellious character, many doubting its milling to any percentage. But, bullion speaks for itself, and now since Mr. Howell has demonstrated what can be done with the property in putting it into the shape of a paying proposition, he will move himself in interesting capital toward putting up a mill of large and adequate capacity at Hiko, which the property fully warrants and justifies. The removal of the little mill from the mines of Pahranaagat valley is a severe blow to the miners there. True, the mill was only a 5-stamper, and at the place it was erected but a sufficient quantity of water could be obtained to run but twelve hours out of the twenty-four. It was but little better than nothing to the miners, but that little helped so much, and now, being deprived of it, they are left in a sorry plight, as the ore is of such a quality that it will not pay to ship to Salt Lake, yet it paid a handsome profit when worked near the mines. It is to be hoped that arrangements can be made so that Mr. Howell will be able to lease the mill at Hiko on fair terms. The mines there are now showing well, the quantity and quality of the ore being good.

Tuscarora District.

WILL NOT START UP.—Times-Review, Nov. 19: There was a report around town that the Grand Prix mill would start up in a few days. We are informed by Superintendent Dixon, however, that such is not the case. The ore, to save two handlings is taken direct from the mine to the mill, and that probably gave rise to the rumor. There is considerable amount of fair grade ore being extracted, and probably the mill will start up sometime during the winter, there being sufficient fuel, etc. on hand for several months' run. Work was resumed at the Central Con. this morning. The engine was started up and preparations are being made to start a drift west at the 80-foot level to strike a body of ore that there is reason to believe lies in that direction. Only a day shift will be run at present.

Taylor District.

BULLION.—Cor. Eureka Sentinel, Nov. 20: The Argus Mining Company and Monitor Mining Company of this district are looking better, and as bullion shipments speak for themselves, no puffing is necessary. We have several outside promising districts, which will attract attention next summer.

ARIZONA.

TAILINGS.—Prescott Courier, Nov. 18: Messrs. Cartmell and Hughes have finished running through the tailings at the old Aztlán mill, on Groom Creek, and, as we understand, have made a handsome profit out of their venture. Too much credit cannot be given to Mr. Cartmell for his ingenuity and perseverance in putting together and refitting the burnt and distorted machinery that lay amidst the ruins of the mill. Looking at them as they were eight months ago, not one man in a hundred, with Cartmell's limited means, would have had the pluck to take hold of them, or the ability to do anything with them. Mr. Cartmell will have his ten stamps at work early next month on a lot of ore from the Happy Jack mine, on Lynx Creek, which he has purchased from Hugo Richards. Doctor Farnham went out to Lynx Creek, yesterday, to turn his five-stamp mill into a dry crusher. The doctor reports his discovery of a very rich gold lead on his Iron Clad claim.

COLORADO.

SHUT DOWN.—Elk Mountain Pilot, Nov. 19: The Avery mill at Gothic has shut down for the winter, and the Sylvanite mine will ship from 150 to 200 tons of ore outside just as soon as they can haul it. The mill at Gothic is a success and all right with the exception of some alterations that are needed in the roaster. In order to make these changes it would require several weeks to get the new machinery here, and Mr. Avery deemed it best to close the

mill until next spring, when the changes will be made that will probably make the mill a complete success. What ore was run through the mill from seventy to ninety per cent of the silver was saved, which is a very good saving. The Sylvanite mine is now producing very good ore which is found in the vein that is more solid and not broken up. We regret to announce that the Hewson tramway to the Augusta mine will not be completed this winter owing to the weather being unfavorable at that altitude. The Queen of the Gulch, in Dark Canyon, is being worked by contract. This property is owned by a Pennsylvania company, and Joseph McCullough and L. L. Howe have a contract to run the tunnel on the vein 100 feet. The tunnel is now about 65 feet long. There has been more rustle among the miners this fall than usual, and Rock Creek is attracting the attention of capitalists. Our mines and marble interests are bound to come to the front. The Black Queen keeps taking out a quantity of splendid ore and shipments are still being made. This property can be classed among the most important in the county. Work has been started up on the Black King, an extension of the Queen. This is a large vein and croppings similar to the Queen. The Lost Horse has struck harder ground but is being pushed ahead. I. G. Sanbrough has been putting things in shape for the winter, and will open up his property on Lost Trail creek. Henry Redden is hard at work on his property and has a good showing. He is one of the stand-bys of the camp. Ed. Skinner is working the Cape Briton. Several claims have been patented this season around camp and work will probably be started upon them. Our marble properties will probably change hands in course of a short time and we will see another industry started up that will be of great benefit to our county and State.

IDAHO.

BAY HORSE.—Cor. Salt Lake Tribune, Nov. 20: The smelter closed for the season, and but little being done in the mines. The cause of this is largely due to the litigation between the Beardsley and Excelsior companies. Bay Horse was never more prosperous than just before these court proceedings began last spring, and now her future is badly clouded. It is a pity that a camp with so many good properties developing should have such a shadow cast over it, and we can only hope for an early solution of the troubles and for the coming of brighter times than ever. The closing down of the smelter stops most of the work at the mines. The smelter has sent out a large quantity of bullion during the season, the merchants have done well, and there has been considerable improvement in the town. Clayton, located eighteen miles farther up Salmon River, has had a prosperous season. The smelter, operated by A. J. Crook & Co., has sent out forty cars of bullion, ten cars of first class ore and matte, making in all about 500 tons. The smelter is operated by water, and averaged 22 tons of ore per day, and has given employment to 20 men at works, 75 in coal camps, and 65 at the mines owned by the company. They own some good mines, and their operations next season will be extensive. The smelter will close for the season about the 15th. Bonanza and Custer are quiet towns now, having gone into winter quarters. The Custer Company is crushing thirty tons of Badger ore per day, giving employment to thirty men in the mill and fifty in the mines, timber, etc. They are working \$40 rock at a profit. Chris Morler, the superintendent, appears to be a good man for the place, and looks well after the interests of his company. The Dickens mine is partly filled with water, and being tied up in suits, is lying idle. The Montana did a large amount of dead work the past season in the way of running a lower tunnel to drain the mine. They took out sixty tons of \$300 ore and had it worked at the Custer mill. The interest belonging to D. B. Varney was sold a few days ago to satisfy a judgment, and was bid in by A. and J. Pfeiffer, after which the ten men employed were discharged and the property closed till next season. J. G. Morrison took out about \$1,500 from his placer claim and did a little work on his Washington and Paradise claims. The former has very rich ore, and ought to be in the hands of a good company to operate. The Whale had a few tons of ore worked in the spring, but is now lying idle. Pfeiffer Bros., at Bonanza, and J. H. Lee & Co., appear to have a lucrative trade in general merchandise, each carrying a heavy stock. The Yankee Fork country possesses many good ledges, but has been unfortunate in not getting adequate capital to operate with.

THE CROCUS MINE.—Wood River Times, Nov. 18: The Crocus mine, in Scorpion gulch, continues to improve with every foot of development. The incline is down 135 feet, and a drift runs on each side at that depth. The ore vein is two and a-half to three feet in width, and the ore averages \$30 per ton in gold and \$7 to \$9 in silver. When concentrated the result is \$80 to \$90 ore. There is about 100 feet of ground in the mine that is opened and can be stopped clear to the surface. There are about 12 men at work in the mine; with the teamsters, contractors, and leasers included, 20 men are kept at work on the Crocus ore, and the property pays a good profit, besides its own development. The lessees are Chase & Hodgman, who own the concentrating works at Indian creek. They intend to work all winter, and will evidently make considerable money on their lease while opening up a good property.

MONTANA.

BUTTE.—Miner, Nov. 18: Copper mines of Butte are working at a small profit, and can continue to do so at these prices, but the sole reason is on account of the facilities for working both mines and furnaces. The hopeful views given above are entertained by all friends of copper mining, and a realization of the same is most heartily to be looked for. In and around Butte there is the same general run of news to report this week from all the mines, with nothing of a startling nature to enliven the mass of flattering appearances. The mines and furnaces are plodding along with their accustomed energy, and there is no decrease in the output of either, nor is there an unusual increase. The following is a summary of the regular weekly visit to the various properties mentioned: Moulton.—The main shaft is down 35 feet below the 600 foot level, and sinking is

going steadily ahead. The ground is hard, and there is no perceptible increase in the flow of water. It has not yet been necessary to start up the pumps, as the tank handles it without any trouble. The stopes are producing as much ore as ever, and all of the company's machinery is in first-class working order. Alice.—The drifts on the 800 level are both in good ore, which is being taken out and milled, the assay value being above the average. Sinking has been suspended, awaiting the arrival of the new bob for the pump. The bob-pit on the 800 station is cut and ready for the reception of the machinery. Both mills are running to their full capacity.

OREGON.

QUARTZ.—Grant's Pass Courier, Nov. 20: Messrs. McCallister & Stanley are now down on their ledge on Rogue river 40 feet and have a well defined vein some eight feet wide, with a gouge of 3 to 18 inches. Some of the assays run as high as \$300 per ton. The vein now appears to be turning and dipping into the hill. The sinking of the next 10 feet will be watched with great interest, as the vein will then in all probability have its true pitch and a very fine body of ore may be looked for. The Stanley mine on Evans creek, is one of the best prospects in this section. It is down about 10 feet with well defined walls and carries a large amount of copper, with gold through the whole vein. We are in hopes that work will be prosecuted on this vein. The Eastman ledge situated a mile below this town is down about 12 feet. It shows some copper stained ore. Some rich float has been found on the other side of the river near the Jewett ledge, and parties are in hope that they will shortly strike the vein. Messrs. Brown & Walker are now engaged in opening up their claim at the mouth of Green creek. Their ground prospects most favorably, and they will shortly put on a hydraulic and work it on a large scale.

DRY DIGGINGS.—Several miners are now engaged in drifting with very fair returns. This is a never failing source when men wish to make a small raise; the ground paying uniformly small wages.

THE GRAVE CREEK.—The Steam Beer Gravel Claim Company have made a large reservoir, and have lowered the flume and with the present prospects for water will no doubt make a better showing than they have for years.

BRIMSTONE.—This old and well known claim now leased to Mr. Davis is now in better condition for a good winter's run. Much ground has been burned and cleared, and we shall be surprised if it does not this year yield as it has of yore. The Goff gravel claim has enlarged its ditches, built a reservoir, and it is now in very interesting ground—very heavy gold having been struck just prior to their closing down last year for want of water, we may look for very valuable developments. The Maloney Bros. are mining to some extent. If capitalists would only extend a ditch to this, there are 200 acres of ground that every tool will pay with a pipe and ample fall.

LOUSE CREEK.—The Van Peer ledge is down some 15 feet. The mine has never been prospected as it should be; the ore running high in fine gold.

MILL.—Oregon Sentinel, Nov. 20: A quartz mill in Jacksonville is now an assured fact as nearly the full amount asked for as a bonus has been raised. The terms of contract call for an \$8000 mill and Mr. L. D. Brown expects to start below to-morrow night to order it.

AT WORK.—Jacksonville Times, Nov. 20: Dan Hunt informs us that many of the miners of Josephine county are at work. Wimer & Sons' mines near Waldo, as also Deselles & Connell's, are running on full time. The Melford reduction works are now in running order and are testing ore from different mines. At Wm. Clark & Co.'s claim in Alt-house, Josephine county, a \$50 slug was picked up not long since. Simmons, Ennis & Co.'s huge enterprise is not moving at present, though active operations will no doubt be begun soon. Thos. Berryman, who has been drifting for several years on Applegate, has struck another good pay-streak and is doing well. Very few of the miners in Jackson county are at work yet, owing to the scarcity of water. A few days' rain would set all of them going, however. Boyd & Johnson are now prospecting a quartz ledge in the Blackwell district, which prospects well in silver. They sent some of the ore East for assay, and the returns are quite flattering. C. W. Triplett recently finished a large reservoir on the Steam Beer claim on Grave creek, owned by Rast, Critser & Fullerton, which will enable them to make a much more extended run than usual. Considerable prospecting is still being done in different portions of Jackson and Josephine counties. When the quartz mills at Jacksonville and Medford are in operation, there will be much more inducement to prospect for quartz. H. E. Ankeny went down to Galice creek recently with a representative of a Chinese firm, who are negotiating for the Ankeny hydraulic claim in that section. This is an extensive mine, but has not been worked profitably for some years past.

UTAH.

REVIEW.—Salt Lake Tribune, Nov. 20: The week has been devoid of special feature, but the mild and clear weather has permitted activity in getting the ores to market, and the output has been large. The receipts of bullion and ore in this city for the week ending November 18th, inclusive, were, of bullion, \$86,657.57; of ore, \$22,610, a total of \$109,267.57. For the previous week the receipts were \$161,962.45 in aggregate, of which \$124,314.65 was in bullion and \$37,647.80 was ore. The output of the Ontario for the week was \$34,444 in bullion, raising its aggregate for the present year to \$1,441,463.21. The Stormont sent up two bars of silver on the 14th, \$2960. The product of the Hannauer smelter for the week was eleven cars, \$28,210; of the Germania, ten cars, \$24,013.57. There is nothing from the Horn Silver, but it is given out that the superintendent expects to tap the ledge through the new workings, about the first of the year. Ore receipts were \$5800 from the Crescent, \$3690 from the Lead mine, \$2980 from the Sampson, \$2100 from the Spanish, Utah, \$6500 from the Queen of the Hills, \$1700 from the Mayflower, Idaho,

THE GIANT POWDER COMPANY

Manufacture Three Kinds of Powder, which are acknowledged by all the Great Chemists of the World as

The Safest and Strongest High Explosives in the Market.

GIANT POWDER or DYNAMITE,
Of Different Strengths as Required.

NOBEL'S EXPLOSIVE GELATINE," which contains 94 per cent of Nitro-Glycerine, and

Scientific Press

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

without roasting. Leaching of silver ores. Chlorination
of gold sulphurets. Assaying, Chemical Analyses of Ores,
Metals and other substances.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the **IMPROVED FORM OF HYDRAULIC GIANTS**, which we manu-
facture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under
the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et als.

Prices furnished upon application to

JOSHUA HENDY MACHINE WORKS,
38 to 51 Fremont St., San Francisco, Cal.

This cut represents our

**IMPROVED
HYDRAULIC
MACHINE.**

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT
instead of two. It is of greater capacity and more easily worked and
kept in repair. The statement of Mr. Hendy that all styles are infringe-
ments on the machines made by him, he knows to be utterly false. All
litigation has been in reference to old style two jointed machines, which
are superseded by our new style one jointed. The decision of Judge
Sawyer, referred to by him, is carried up on appeal to U. S. Supreme
Court, with absolute certainty of a reversal in our favor. Send for
Circulars and Price List.

HOSKIN & CO., Marysville, Cal.

PATENT LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning
and Salivation

The most perfect appliance for people engaged in
Smelting, Dry Crushing, Guano Works,
Quicksilver Mines, Lead Corroding, and all
other occupations where there is dust, poisonous vapor,
or bad odor.

In Feeding Threshing Machines, and similar
work, they are indispensable, as no foreign substances
can be inhaled when they are worn.

The Respirators are sold subject to approval after trial,
and if not satisfactory the price will be refunded. Price,
\$3.00 each or \$30.00 per dozen. Sent post-paid to any
address on receipt of price.

Address communications and orders to

T. E. JEWELL, Sole Agent,
330 Pine St. (Room 4) San Francisco.

Send for Descriptive Circulars containing Testi-
monials of well-known parties who are at present using
them.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over
other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impos-
sible to make them tight except by regrinding, which is expensive if done by hand, and if don-
by machine soon wears out the valve, and in most cases they have to be dis- connected from
the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is
manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited.
To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

DUNHAM, CARRIGAN & CO., San Francisco, Cal.

American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Mining Share Market.

The rise in the Carson river, which gives all the mills a chance to run, is making Comstock matters look up considerably, though stocks in this city remain about the same. All the mills, large and small, along Six-mile and Gold canyons, are now well furnished with motive power, and are running full blast. In the mines the effect of this increase of milling facilities is already beginning to become perceptible. More men are gradually being put to work in the extraction of low-grade ore, and the shipment of ore over the railroad correspondingly increased. There is a vast amount of this low-grade ore in the upper workings of the mines, especially at the Gold Hill end, and also at the north end and the old bonanza sections of the Consolidated California and Virginia, and its working is merely a matter of practical solution as to whether it can be made a paying proposition at the present cost of extraction and milling. There is a huge vein of low-grade ore extending from the Yellow Jacket through the Imperial, Exchequer and Alta to the Bullion mine for over a thousand feet in depth and near the surface, and this will be eventually explored and made available if it can be made to pay. But poor men cannot work it and capitalists will not, unless they can make it pay. This low-grade ore proposition is very naturally connected with the future sustenance and prosperity of the Comstock.

Active and effectual work is going ahead in the middle mines, following up the prospects of developing another rich Comstock bonanza. Thus far, however, only rich veins and bunches of ore have been met with.

At the south or Gold Hill end more men are occasionally being put to work as required. One or two small drafts of miners have been made recently in Yellow Jacket and Crown Point, yet these were merely temporary affairs. More men will be worked as eligible opportunity and the encouragement of paying ore offers.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco.

GOLDEN GATE PRINTING AND PUBLISHING CO., Nov. 21st.—Object: Carrying on a general printing and publishing business. Directors: Amos Adams, R. A. Robinson, Robert Brown, M. B. Dodge and J. J. Owen. Capital stock \$15,000, in shares of \$5 each.

KELLOGG MALLEABLE STONE PAVING CO., Nov. 25th.—Object: Manufacturing malleable stone and concrete macadam to be used in street and other paving. Directors: F. H. Kellogg, C. W. Beach, A. S. Reid, Henry F. Williams and D. A. Macdonald. Capital stock \$50,000.

Bullion Shipments.

Lapanta, Nov. 18, \$10,000; Germania, 17, \$4870; Ontario, 17, \$31,444; Hanauer, 17, \$5140; Queen of the Hills, 17, \$3900; Spanish, 17, \$2100; Hanauer, 18, \$3160; Crescent, 18, \$3100; Lead, 18, \$1500; Germania, 19, \$4856; Hanauer, 19, \$2570; Samson, 19, \$2980, Crescent, 19, \$2700; Queen of the Hills, 19, \$1300; Hanauer, 20, \$2610; Queen of the Hills, 20, \$1165; Germania, 21, \$4421; Hanauer, 21, \$5140; Stormont, 21, \$2800; Lead, 21, \$1200; Germania, 22, \$4278; Hanauer, 22, \$2750; Queen of the Hills, 22, \$1400; Bannock, 22, \$2247; Alice, 22, \$24,832; The banks of Salt Lake report the receipt for the week ending Nov. 18th, inclusive, of \$86,657.57 in silver and \$22,610 in ore, a total of \$109,267.57.

...SOLE MANUFACTURERS OF...

**KENDALL'S PATENT
QUARTZ MILLS.**

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are now enabled to offer these mills at GREATLY REDUCED PRICES. Having made and sold these mills for the past five years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap, and durable mill that will do all that claimed for it and give entire satisfaction.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

THE ROLLER ORE FEEDER

[Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

\$1,000 CHALLENGE!

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS!
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

RANKIN, BRAYTON & CO.,
BUILDERS OF
MINING MACHINERY.

San Francisco: 127 1/2 St. Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

DRY WASHER for PLACERS

THE HITCHCOCK & HERSHEY
NEW DRY GOLD CONCENTRATOR.

This Machine weighs only 325 pounds; readily taken apart; packs in small compass; may be run by hand or horse power. Capacity, two tons an hour. No blowers or 6x1 fans, or quicksilver used. Frame all malleable iron. Will save a higher percentage of gold than other machines. TATUM & BOWEN, San Francisco and Portland, Agents.

Now on exhibition at Mechanics' Fair, San Francisco, where it may be seen in operation.

ANNOUNCEMENT.

The Clayton Air Compressor Works, of Brooklyn, have opened an office at No. 43 Dey Street, New York, for the sale of the Clayton Improved Air Compressors, Rock Drills, Mine Pumps, Hoisting Engines, Rock Crushers, Blasting Batteries, Wire, Fuse, and Mining Machinery in General. For Catalogue—August 1885—estimates and general information call upon or address, Clayton Air Compressor Works, Office, 43 Dey Street, New York.

[From the Engineering & Mining Journal, Aug. 8, 1885.] The Clayton Air Compressor Works have issued a New Illustrated Catalogue and Price List. Every Mine Manager and Engineer should have a copy for reference, for none can afford to be without the information there given concerning the unsurpassed Clayton Air Compressors and other Machinery.

VOLUME LI
Number 23.

The Late Peter Donahue.

The engraving on this page is a very good likeness of the late Peter Donahue, who died in this city last week, and who was one of those sterling and progressive characters of which California has furnished so many examples. From a plain mechanic, working in a shop, he grew by his own exertions to a millionaire, in control of great undertakings. He was one of those to whom San Francisco owes much. Having made his fortune here he continued his investments or undertakings in the States, most of them tending largely towards our industrial advancement.

In early days a miner, he shortly afterwards turned his attention to mechanical pursuits, building saw-mills, working at the blacksmith's forge, making boilers, etc. He established the first iron foundry in this city, and made the first casting ever molded in California. In those pioneer days he established the shop which afterwards grew into the great Union Iron Works, now the largest establishment on the coast. When these works were removed from the old place, on the corner of Mission, First and Fremont streets, not very long since, he commenced the construction on the old site, of what will be one of the finest buildings in this city.

The originator of the present system of supplying San Francisco with gas, Mr. Donahue continued until his death his large interests in the company. He was an extensive builder of railroads, being the principal owner of the San Francisco and North Pacific, with its ferry lines. The railroad from this city to Gilroy, 80 miles, was built by him and afterward sold to the Southern Pacific. He was the originator, too, of the first street railroad in this city. On page 375 of this number of the PRESS is a more extended sketch of Mr. Donahue's life. He was a director of the Hibernia Bank, and had been for over 20 years. He was also a director of the National Gold Bank, and of the State Investment and Insurance Co. Mr. Donahue was President of the Society of California Pioneers in 1872-73, being up to that time the youngest President the society ever had.

Mr. Donahue carried a reputation for the strictest integrity and made many friends. His funeral was one of the largest ever seen in this city, for a private citizen. The engraving, for which we are indebted to the courtesy of the *Resources of California*, is a good representation of Mr. Donahue's countenance.

FOREIGNERS AND PLACER CLAIMS.—The Supreme Court has decided that no foreigner who has not at least declared his intention of becoming a citizen can acquire title to a placer mining claim. The decision is the result of an appeal against a decision of the Superior Court in the case of Lee Doon et al. vs. Tesh, which involved the title to the Clark & Co. placer claim in this State. William McConnell, one of the plaintiffs, is excepted from the effect of this decision, having conformed to the requirements of the law in the matter of citizenship.

The report of the Government officer who visited Granite Creek (B. C.) mines is published. He gives a glowing account of the prospects for miners there. He saw \$400 taken out in a rocker in a single afternoon by two men. Several claims are yielding from \$250 to \$400 a day.

A College of Science and Mining for Dakota.

At the last session of the Legislative Assembly of the Territory of Dakota, provision was made for the establishment of a School of Mines for Dakota, at Rapid City—the "gates city" of the Black Hills. The object of this school is to furnish facilities for the education

the terminus for the present of the Elkhorn Valley Railway, now completed to Buffalo Gap, only 45 miles distant.

A NEW QUARTZ BATTERY.—A battery on an entirely new plan is soon to be put before the public. An eight-stamp one has already been built, tested and proved so satisfactory that the company owning the patent are now build-

THE LATE PETER DONAHUE.

of such persons as may desire to receive special instruction in chemistry, metallurgy, mineralogy, geology, mining, milling, engineering, mathematics, mechanics' drawing, the fundamental laws of the United States, and the rights and duties of citizens.

A commodious brick building for chemical and mineralogical laboratories has just been completed, at a cost of \$10,000, and will form one wing of the final structure. Instruction in this institution will be free to all citizens of the Territory, of either sex. Arrangements have been made for extensive illustrative collections of minerals and fossils.

Professor W. P. Blake, formerly of the College of California, at Oakland, has accepted the presidency of the institution, and will proceed with its organization.

Rapid City is a flourishing place, and will be

ing one of twelve stamps. The mill is, in every detail as to feed, stamps, dies, stems, shoes and tappets, the same as an ordinary straight battery, at the same time all the heavy and expensive wood-work is dispensed with, and yet the battery sets firm. As soon as the twelve-stamp one is completed we will give our readers more details concerning it. The inventor is Almarin B. Paul, who has had 36 years' practical experience in milling ores—enough, certainly, to bring forth a practical working mill.

P. W. CUNNINGHAM, of Winnemucca, has received an order from John Nelson, of Dun Glen, Nev., for 16 rockers to be used in washing gold-bearing gravel at the new placer mines recently discovered in Barber's canyon, Nev. Very good prospects are found and it is thought the gravel will pay to wash in rockers.

Timber Lands and Mines.

The recent order of the Commissioner of the General Land Office, on which we have commented, seems to have been misunderstood, according to the interpretation that official now puts upon it. He says he has transmitted to the Secretary of the Interior over 30 cases of timber trespasses, reported by special agents, against the Montana Improvement Co., and recommenced suits for the recovery from said company, jointly with the Northern Pacific Railroad Co., of \$750,000 damages to the United States. This company has a stock capital of \$2,000,000, of which the Northern Pacific Railroad is said to own a majority, and is reported to the General Land Office as one of the most expensive and dangerous depredators of public timber in the Northwest.

He denies specifically that he has taken any official action relative to the cutting of timber from mineral lands "for agricultural, mining or other domestic purposes," under the provisions of the Act of June 30, 1878, other than to submit to the Secretary for consideration certain amendments to existing rules, the chief object of which is to prevent the taking of timber in evasion of the law, for speculation and export, and says that these amendments, which are now being considered by the Secretary and himself, do not contain the asserted provision that individuals entitled to take timber must cut it themselves and cannot hire the work done or employ servants to do it. The Commissioner has made no such recommendation.

Gen. Sparks says emphatically there is no truth in the statement that there is coolness between the head of the Interior Department and himself, and that no rules, amended or otherwise, have been promulgated by him that have not been approved by the Secretary. If it is possible to prevent the wholesale cutting of timber on Government lands by corporations, it is to be hoped the officials will continue their efforts. What little a few miners or mining companies cut does not amount to much, and they should continue to be allowed to supply their wants. But when it comes to big companies cutting and selling it, they should be stopped at once.

A new money order system of Wells, Fargo & Co. has gone into effect. These orders will be issued for any amount from \$1 upwards, payable to either the bearer or order in 8000 places in the United States and Canada. Receipts will be given and money refunded should the orders be lost. The orders will be remitted as exchange upon all the large cities of the United States. The following are a few of the rates to be charged: From \$1 to \$5, 5 cents; over \$5 to \$10, 8 cents; over \$10 to \$20, 10 cents; over \$20 to \$30, 12 cents; over \$40 to \$50, 20 cents.

The Ontario Mining Company, of Utah, paid \$75,000 in dividends on the 30th ult. This is the twelfth dividend this year, an extra one having been paid in October, making \$900,000 since January 1st, equal to \$6 per share. Since incorporation there have been 144 dividends, amounting to \$6,950,000. The Ontario is the longest lived and most prosperous silver mine now being worked in this country.

The Small Hopes Mining Company of Colorado paid \$687,500 in the first nine months of the year.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eos.

Mineral and Metalliferous Veins.

How Formed, How Filled, and Where Found.

EDITORS PRESS:—Most metals occur in veins associated with certain minerals. All rocks, but especially metamorphic rocks in mountain regions, are seamed and scarred in every direction, as if broken and again mended, as if wounded and again healed. All such seams and scars of whatever nature and by whatever process formed, are known by the general name of veins.

In this article, "dikes," or those kinds of fissures that were filled at the moment of formation by igneous or eruptive injections, will not be considered. True veins, he it noted, are accumulations, mostly in fissures, of certain mineral matters usually in a purer form than they existed in the rock. The accumulations have in all cases taken place slowly. Veins are of three kinds: veins of segregation, veins of infiltration and great fissure veins. Some writers claim many other kinds, but these may be regarded as intermediate varieties.

Veins of Segregation.

In these the vein matter does not differ greatly from the inclosing rock. There seems to be no distinct line of separation between the vein and inclosing rock—"no distinct wall to the vein." The reason is, apparently, that these veins are not formed by the filling of a previously existing fissure, but by the segregation or concentration of certain materials in certain spots or places and at certain lines in the rock, either when the latter was in a plastic condition from heat and water, or else by means of percolating mineral solutions after the manner that concretions of lime, clay, flint, iron-ore and geodes are formed in strata.

Veins of Infiltration.

Metamorphic rocks have, probably in all cases, been subjected to very powerful horizontal pressure. And more—the wide folds into which such rocks are thus thrown and the great fissures thus produced, the strata are often broken into many sections by means of the great squeezing and crushing. The small fissures thus produced are mostly filled by "lateral secretions" from the walls, or else by percolating waters holding in solution the more soluble matters contained in the rocks. The process is similar to the filling of a cavity left by some organism (fossil casts) and still more to the filling of air-blebs in traps and lavas, and the formation of agates, carnelian, zircon, zeolites and amygdulæ of various kinds. In veins of infiltration, therefore, a beautiful ribbon structure is often produced by the successive deposition of various-colored materials on the walls of the fissure. Veins of this kind also, since they are the filling of previously-existing fissures, have well-defined walls. The filling consists most commonly of silica and calcite, both of which are often the matrix or gangue, containing metallic ores. Veins of this kind, therefore, often make good paying mines, but not so good as great fissure veins. The latter we will now consider.

Great Fissure Veins.

These are fillings of the great fissure, produced by extensive movements of the earth's crust. The most obvious characteristics of the veins of this class are their size, their continuity for great distances and to great depths, and their occurrence in parallel systems. As the vein is a filling of a previously existing fissure, the distinction between the vein and wall-rock is usually well marked. The contents of fissure veins are also far more varied than those of other kinds.

Metalliferous Fissures.

All the kinds of veins mentioned above may contain metals, but the segregative veins are usually too irregular and uncertain, and the infiltrative veins too small and limited to be greatly profitable. True, profitable metalliferous veins are almost always great fissure veins. The contents of such are of two general kinds, viz., vein-stuffs and ores. The principal vein-stuffs are quartz, calc-spar, carbonate of iron, heavy spar, fluor-spar, and carbonate of baryta. But by far the most common of these is quartz, and next is calc-spar. Often, however, the vein-stuff is an aggregate of minerals forming a true rock. Most of the vein consists usually of vein-stuff. The ore exists in comparatively small quantities, sometimes forming a central rib or sheet, sometimes in irregular, isolated masses, and again in small strings, or seams or grains, scattered irregularly through the vein-stuff, and sometimes extending a little way into the wall rock. The "chemical forms" in which metals occur are very various; sometimes as pure metal (as always the case of gold and platinum, and sometimes in the case of silver and copper), but more commonly in the form of metallic sulphides, metallic oxides and metallic carbonates. Of these the sulphides are by far the most common, and the latter seems to have been the original form or state, from which the former subsequently changed, "evidently an evolution of chemical affinities in accordance with immutable, natural laws." These multifarious changes, during long periods of time, have cul-

minated in the production, in available forms, of all the various metals and minerals that are now utilized by our race. But regardless of all that exists and of all the long time necessary for its production, it is not the easiest job in the world for a prospector to find a good mine. It is seldom accomplished, as you all know, even by the luckiest and pluckiest of Nature's noblemen. Your pardon for this digression, and I will resume my subject.

Irregularities of Fissure Veins.

Although more regular than other kinds, yet fissure veins are often quite irregular, sometimes branching, sometimes narrowing or pinching out (walls almost in contact), again widening and dividing in such a manner that it takes a mining genius to follow them. These irregularities are probably the result of movements after the fissure was formed, or even after it was filled.

How Formed.

The cause of great fissures is evidently always movements, and usually foldings or wrinklins of the earth's crust, produced evidently by the contraction of its interior. Accepting the "nebula hypothesis" of the globe, it is logical also, to infer "a secular cooling," whereby the contraction of the interior causes fissures to be broken, through some portions of its crust. This usually occurs in mountain regions in which, also, most great fissures are found. The facts being thus, we will say no more on that subject, but consider how these veins are filled.

How Filled.

The contents of mineral and metallic veins were deposited from hot alkaline solutions, or hot mineral waters, coming up through fissures. The vein-stuffs, especially quartz, and the metallic ores, especially the sulphides, were thus deposited. They were deposited from solutions, as the beautiful crystals so often found in veins could be formed in no other way. The quartz of veins is always of the variety having a specific gravity of 2.6, and therefore was produced by slow deposit from solution. The fluid cavities, so often found in quartz vein stuff, are a proof of formation by humid process. The solutions were hot: fissures extending deep into the interior of the earth could hardly remain empty of water, and from their great depth the contained waters must be hot. Now, the solvent power of water, when heated and under pressure is well known. Scarcely any substance wholly resists it. The invariable association of metalliferous veins with metamorphic rocks demonstrates the agency of heat. The solutions were alkaline. Alkaline carbonates and sulphides are the only natural solvents of quartz, the most abundant of vein-stuffs. Now there seems no reason to doubt that in most cases at least, and probably all cases, that vein-stuffs, or the contents of veins were deposited from hot alkaline solutions. And further, it is evident, from their intimate association with the vein stuffs, that the metallic ores were deposited from the same solution. There seems little reason to doubt, then, that all mineral and metalliferous veins are fillings of previously existing fissures, and that their contents have been deposited from hot alkaline waters, holding the various mineral substances in solution. This conclusion, endorsed by various scientists, is, also, strongly supported by the phenomena of hot alkaline springs in various portions of the world, as well as the additional proof shown by the Geysers, in the National Yellowstone Park and elsewhere on the globe. In short, to be brief, once conceive clearly that mineral veins are simply filled water-ways, and all these complex phenomena solve themselves.

Where Found.

Usually metalliferous veins are far more numerous in mountain regions, and especially in metamorphic rocks. This is owing to the fact that at such places and in such rocks their existence is made possible. But to be brief and definite on this subject, as my space is limited, I will conclude this article with the remark that metalliferous veins—good, bad or indifferent, are found only where they exist, and from the experience of most prospectors, it is claimed that the "good ones" are even hard to find where they do exist. Probably they are very near the truth.

CHAS. F. BLACKBURN.
Blackburn Mining Dist., Idaho Territory,
Nov. 24, 1885.

Fine Gold.

EDITORS PRESS:—I have lately noted a fact regarding the gold coming from a number of quartz mines in the immediate vicinity of this town that may interest your readers. I refer to the unusually high fineness or value per ounce of the gold—higher, I believe, than that of any other gold mines in this State, and as far as I know, of any quartz gold mines in any country. I will give but two instances. The fineness of the gold from the San Giuseppe mine is .983, equal to \$20.32 per ounce. That from the Neale mine is .950, equal to \$19.64 per ounce. When we consider that the value of chemically pure gold (1000 fine) is \$20.6718 per ounce, the close approach to absolute purity of the gold from the mines is worthy of note.

I do not refer to river gold or placer gold, but to gold found *in situ* in quartz, and I do not believe that the mines of any country—domes-

tic or foreign, can show equal fineness—certainly not equal to that of the first named mine—the San Giuseppe.

If such do exist and they are known to miners in California or elsewhere, it would be interesting to learn their names and localities, and I trust they will send the figures to your paper for publication.

Experiments in Roasting and Amalgamation.

(Continued from our issue of November 21st.)

Summary of Results.

These experiments present many interesting features. They show: First.—That a mere oxidizing-roasting leaves a large percentage of the magnetite intact, and that a continuation of the process is of very little benefit after the pyrites have been roasted dead. Some aluminium sulphate, resulting from decomposition of the garnet, remains undecomposed, a salt that would not interfere with any treatment to which the ore may be subjected. Second.—A direct chloridizing-roasting removes the magnetite almost completely, and very rapidly. Third.—If the chloridizing-roasting is continued beyond a certain time, magnetite is reformed, cuprous chloride becoming oxidized by withdrawing oxygen from ferric oxide. This is very evident in charge No. 5.

Loss of Gold in Chloridizing-Roasting.

It remains, however, to record the most remarkable results of these experiments. In determining the gold value of the ore, before and after chloridizing-roasting, I found an enormous loss of this metal by volatilization. These results were so entirely unexpected that I first concluded an error had been made in the assays. Such was not the case, and in repeating the experiments, by roasting in a muffle, the facts were established beyond any doubt. In the latter case, well mixed samples were carefully assayed, and then one assay-ton mixed with three per cent salt, and roasted for one hour.

Charges Roasted in the Reverberatory Furnace.

No. of Charge.	Gold Value, Before Roasting.	Gold Value, After Chloridizing-Roasting.	Gold Loss, In per cent.
No. 2.	0.916 oz. p. t.	0.426 oz. p. t.	53.5
No. 4.	0.262 "	0.150 "	42.8
No. 5.	0.538 "	0.075 "	86.1
No. 6.	0.650 "	0.075 "	88.5

Charges Roasted in the Muffle.

No.	Gold Value, Before Roasting.	Gold Value, After Roasting.	Gold Loss, In per cent.
No. 1.	0.700 "	0.050 "	93.0
No. 2.	0.525 "	0.075 "	85.7
No. 3.	0.650 "	0.065 "	90.0

There is no doubt that the volatilization of the gold takes place with that of the cuprous chloride. It increased with the quantity of cuprous chloride formed, and then volatilized and decomposed. It is also a function of temperature.

Finally, I am convinced that the magnetite, as a contact reagent, plays an important part in causing this loss, a fact that invites further investigation. I have no doubt that instantaneous roasting in a Stetefeldt furnace would reduce the loss to a minimum, but even here it might be very perceptible. That the condensation of volatilized precious metals is a most difficult task, is well known to metallurgists. Otherwise we would have here a most simple and perfect method to extract not only gold from the Las Minas ores, but gain considerable copper besides. I abandoned chloridizing-roasting in subsequent experiments altogether.

B. Amalgamating Experiments.

Taking into consideration the low grade of the Las Minas gold ores, the high price of salt and chemicals in Mexico, and the local resources and facilities of the country generally, I became convinced that extraction of the gold by amalgamation, after previous roasting, would be the only economical process. With this object in view, the following experiments were undertaken. In experimenting with such gold ores there are only two ways possible: Either to work very large quantities, or to make tests on such a small scale that the results possess analytical exactness. The latter course was the only one that could be pursued. These experiments being somewhat novel and surprising in their results, it will be necessary to enter into details. The apparatus used consisted of one iron mortar, five inches in diameter, with a rather flat bottom (F. M.); one iron mortar, five inches in diameter, with a concave bottom (C. M.); and one wedgewood mortar, with concave bottom (W. M.). In grinding the charges, the iron mortar with flat bottom proved to give superior results as compared with the iron mortar with concave bottom—its grinding effect was the best. The iron mortars were used to imitate the work of an iron pan; the wedgewood mortar that of an arastra. I know from experience that results so obtained can be realized in working on a large scale. The charges consisted of five assay-tons of roasted ore (1 A. T.—29.166 gm.). This was ground, or mixed with water and quicksilver, the latter being added either immediately, or after the ore had been treated with other

reagents (10 gm. quicksilver to a charge of five A. T. of ore).

The charges were amalgamated either at ordinary temperature or with heating. The latter method had no beneficial effect.

After the amalgamation had been completed the charge was thinned with water, and gently stirred, until the quicksilver was united. For separating the tailings from the quicksilver an enameled iron pan (8 in. diam., on the top, 6½ in. diam. at the bottom, and 1½ in. high,) was used. With a little skill and practice, if necessary, with the aid of potassium cyanide, the quicksilver is easily gathered in one mass, and transferred to a beaker-glass. It is now dissolved in nitric acid. Here the following phenomena are observed. In case only a trace of copper, and very little silver, has been amalgamated, the gold remains at the end of the operation as a spongy globule that can be easily transferred to a drying-cup. The gold so obtained is, however, not pure. It may contain some silver, and enclose particles of tailings. The gold must be packed into a piece of lead-foil, inactivated with silver, cupelled, and the alloy redissolved in the customary way. If considerable copper has been taken up in amalgamation, the gold appears as an exceedingly fine powder—after solution of the quicksilver. It is necessary to filter the solution, collect the gold on the filter, incinerate the latter, and cupel the ashes as above. The presence of a large amount of silver produces a similar but less pronounced effect, and also in this case filtering must take place. It will be seen that these tests must give a positive and very accurate result. That in every instance the gold value of the charges was ascertained in the most careful manner, and all reagents tested for their purity, is hardly necessary to mention. In all 51 charges were amalgamated, and those giving the most interesting results are recorded below.

No. 1.—Roasted San Anselmo ore, from charge No. 1 of "roasting experiments." It contained 39.6 per cent magnetite. No copper sulphate present. The charge had been roasted for 16½ hours. Time of amalgamation three hours, with quicksilver added at once. Time of settling one-half hour. (Time for settling the same in all subsequent experiments.) Value of ore 0.916 ounces gold per ton. Extracted 0.195 ounces gold per ton, or 21.2 per cent.

No. 2.—San Anselmo ore, from charge No. 5, roasted chloridizing. It contained 5.6 per cent magnetite, and a very slight amount of cuprous chloride. Quicksilver added at once. Time of amalgamation one-half hour. Value of ore 0.075 ounces gold per ton. Extracted 0.060 ounces gold per ton, or 80 per cent.

No. 3.—San Anselmo ore, from charge No. 1, sifted through a No. 80 screen. It contained 26.6 per cent magnetite. No copper sulphate. Grinding one hour; then quicksilver added. Time of amalgamation 2½ hours. Value of ore 0.450 ounces gold per ton. Extracted 0.125 ounces gold per ton, or 27.7 per cent.

No. 4.—The same ore as in No. 3. Grinding one hour; then 1.5 gm. mercuric chloride added, and a few drops hydrochloric acid (Designolle process) and worked for three-quarters of an hour; then quicksilver added, and amalgamated three-quarters of an hour longer. Value of ore 0.450 ounces gold per ton. Extracted 0.345 ounces gold per ton, or 76.6 per cent. In repeating these charges (Nos. 3 and 4), but without previous grinding, adding quicksilver in one case, and mercuric chloride in the other at once, and amalgamating for 2½ hours ordinary amalgamation extracted 31.1 per cent, and the Designolle process 82.2 per cent of the gold. Further experiments with the Designolle process, in which the mercuric chloride was reduced to 0.5 gm. per charge of 5 A. T., gave less favorable results, extracting only from 51 to 56 per cent of the gold. All the above charges were worked in iron mortars.

No. 5.—Blanket-washings, from San Anselmo ore, roasted oxidizing for 4 hours contained 19.5 per cent magnetite. Copper sulphate completely decomposed. (These blanket-washings were obtained in crushing the 70-ton lot of San Anselmo ore for the purpose of sampling it.) In order to imitate the working of a pan by first grinding without quicksilver, and then amalgamating with raised muller, the ore was ground in the iron mortars for 1½ hour; then quicksilver added, and for one hour amalgamated by stirring with wooden pestles. Value of ore 1.48 ounces gold per ton. Extracted in F. M. 0.82 per ton, or 55.4 per cent. Extracted in C. M. 0.75 per ton, or 50.6 per cent. In the following charges the same ore was ground for three-quarters of an hour, and then quicksilver added, and amalgamated with iron pestles, under grinding for 1½ hours, with these results: Extracted in F. M. 1.40 ounces gold per ton, or 94.6 per cent. Extracted in C. M. 1.09 ounces gold per ton, or 73.3 per cent. Finally, the quicksilver was added at once, and the charges amalgamated for 2½ hours with grinding. Extracted in F. M. 1.42 gold per ton, or 95.9 per cent. Extracted in C. M. 1.23 ounces in gold per ton, or 83.1 per cent.

No. 6.—San Anselmo ore, roasted oxidizing for 4 hours. The raw ore contained 67 per cent magnetite and the roasted ore 31 per cent immediately after discharging no copper sulphate was present, but after cooling it appeared to some extent, undoubtedly in consequence of the presence of aluminium sulphate. (Quicksilver being added to the charge, the amalgamation was continued for 2½ hours. Value of ore 0.800 ounces gold per ton. Extracted in F. M. 0.355 ounces gold, or 44.3 per cent. Extracted in C. M. 0.340 ounces gold, or 42.5 per cent.

(To be Continued.)

SCIENTIFIC PROGRESS.

Relations of Science to the Public Weal.

We give below several interesting extracts from the address of the President of the British Association of Science, delivered at the re-opening of that association at its recent meeting in Montreal. The relations of science to the public weal as well as to literature and art were largely considered. This subject is an important one and the consideration of it is fast engaging the earnest attention of people of all classes in every civilized community. The complimentary reference to what our own Government is doing in this direction is worthy of special notice. We copy as follows:

The importance of promoting science as a duty of statecraft was well enough known to the ancients, especially to the Greeks and Arabs, but it ceased to be recognized in the revival of letters in the fifteenth and sixteenth centuries. Germany and France, which are now in such active competition in promoting science, have only publicly acknowledged its national importance in recent times.

More remarkable is it to see a young nation like the United States reserving 150,000,000 acres of national lands for the promotion of scientific education. In some respects this young country is in advance of all European nations in joining science to its administrative offices. Its scientific publications, like the great paleontological work embodying the researches of Professor Marsh and his associates in this geological survey, are an example to other Governments. The Minister of Agriculture is surrounded with a staff of botanists and chemists. The Home Secretary is aided by a special scientific commission to investigate the habits, migrations, and food of fishes, and the latter has at its disposal two specially constructed steamers of large tonnage.

The Fishing Interests of England and America.

The United States and Great Britain promote fisheries on distinct systems. In this country we are perpetually issuing expensive commissions to visit the coasts in order to ascertain the experiences of fishermen. I have acted as chairman of one of these royal commissions, and found that the fishermen, having only a knowledge of a small area, gave the most contradictory and unsatisfactory evidence. In America the questions are put to nature, and not to fishermen. Exact and searching investigation is made into the life history of the fishes, into the temperatures of the sea in which they live and spawn, into the nature of their food, and into the habits of their natural enemies. For this purpose the Government gives the co-operation of the Navy, and provides the commission with a special corps of skilled naturalists, some of whom go out with the steamships, and others work in the biological laboratories at Wood's Hole, Massachusetts, or at Washington. The different universities send their best naturalists to aid in these investigations. The annual cost of the Federal Commission is about \$200,000, while the separate States spend about \$100,000 in local efforts. The practical results flowing from these scientific investigations have been important. The inland waters and rivers have been stocked with fish of the best and most suitable kinds. Even the great ocean which washes the coasts of the United States is beginning to be effected by the knowledge thus acquired, and a sensible result is already produced upon the most important of its fisheries. The United Kingdom largely depends upon its fisheries, but as yet our Government has scarcely realized the value of such scientific investigations as those pursued with success by the United States.

Less systematically, but with great benefit to science, our own Government has used the surveying expeditions, and sometimes has equipped special expeditions to promote natural history and solar physics. The Department of Science and Art is doing excellent work in diffusing a taste for elementary science among the working classes. There are now about 78,000 persons who annually come under the influence of its scientific classes. The working classes are being roused from their indifference. They show this by their election of scientific men as candidates at the next election. Among these are Professors Stuart, Roscoe, Maskelyne and Rucker.

Value of Science to Commerce—A Lesson for America.

Passing from learned or public professions to commerce, how is it that in our great commercial centers, foreigners—German, Swiss, Dutch, and even Greeks—push aside our English youth and take the places of profit which belong to them by national inheritance? How is it that in our colonies, like those in South Africa, German enterprise is pushing aside English incapacity? How is it that we find whole branches of manufactures, when they depend on scientific knowledge, passing away from this country, in which they originated, in order to engraft themselves abroad, although their decaying roots remain at home?

The answer to these questions is that our systems of education are still too narrow for the increasing struggle of life. The State has al-

ways felt bound to alter and improve universities, even when their endowments are so large as to render it unnecessary to support them by public funds. When universities are poor, Parliament gives aid to them from imperial taxation.

The speaker then went on to show that those countries which were most liberal in sustaining scientific and technical schools were the ones which were taking the lead in all commercial and industrial enterprises.

We must seek by scientific investigation for ways and means to compel nature to reveal her secrets. It is only carrying before us a golden branch plucked from the trees of science that we can hope to excel or even advance in the industrial arts and invention. That country which is the most liberal in its support of institutions of scientific and technical instruction, is the one which will outstrip all others in the modern race of progress.

What American Paleontology Has Revealed.

Prof. Cope has the following on this subject: It is one of the peculiar advantages of the North American continent to the scientist that the geological structures of its great interior is comparatively simple, so that its history can be easily read. It follows that the history of the succession of life is recorded with the same regularity, and may be read by those who will bestow the necessary labor upon it. Those who have, during the last ten years, devoted themselves to this study, have been rewarded by the discovery of the course of development of many lines of animals, so that it is now possible to show the kind of changes in structure which have resulted in the species of animals with which we are familiar as living on the surfaces of the earth at the present time. Not that this continent has given us the percentage of all forms of animal life, or all forms of animals with skeletons, or vertebrates, but it has given us many of them. To take the vertebrates, we have obtained the long-since extinct ancestor of the very lowest vertebrates. Then we have discovered this ancestor of the true fishes. We have the ancestor of all the reptiles, of the birds and of the mammals. If we consider the mammals, or milk-givers, separately, we have traced up a great many lines to their points of departure from very primitive things. Thus we have obtained the genealogical trees of the deer, the camels, the musk, the horse, the tapir and the rhinoceros, of the cats and dogs, of the lemurs and monkeys, and have important evidence as to the origin of man. We have the primitive mammals from which all these kinds that I have mentioned drew their descent, and from which, no doubt, many other lines were derived which we have not yet discovered in North America. Such are the lines of the elephants, the hyenas, the bears, the hogs and the oxen. The ancestors of this strange, pouch-bearing marsupialia, have been found in part. These creatures, now confined (except the opossums) to Australia and its adjacent islands, were at an early period widely distributed over the earth. Some of these are found in the fossiliferous deposits of our plains and Rocky mountains.

ANIMAL AND VEGETABLE FATS.—Dr. Thomas Taylor, a microscopist in the Department of Agriculture at Washington, has been, of late, doing some most excellent work with the microscope. He recently read a paper on the crystallization of butter and fats before the American Microscopical Society, at its meeting in Cleveland, Ohio. A committee of that society was appointed to examine his methods for distinguishing animal and vegetable fats, and, after a four hours' investigation, it reported that every statement he had made was true. His experiments have demonstrated that each kind of vegetable and animal fat has a distinct, typical crystal. He says that the beauty of fat crystals, as seen under polarized light and selenite plate, is beyond the power of the painter to picture. He will soon publish in the *Boston Journal of Commerce* an illustrative article on the subject.

SAND DUNES.—The great sand dunes along the banks of many rivers, and particularly along the shores at the southern end of Lake Michigan, are due to the presence of the *Amphiphila arenaria*, or sand-gathering grass, which possesses a remarkable power of drawing up moisture. Indeed, it may almost be called a miniature water pump, for it is able to keep the earth wet for several inches around it. This wet earth catches and holds the drifting sand. The process goes on, the grass growing and the sand collecting, until a great sand dune is the result.

THE SOURCE OF CARBON IN CROPS.—In a memoir by Sir J. E. Laws it is maintained that while the atmosphere is the main, if not the exclusive source of carbon for crops, the soil is the principal, if not the only, source of their nitrogen.

BONES IN THE SEA.—Bones have been proven to quickly dissolve in sea water. They are consequently seldom obtained during ocean dredgings, although teeth, which resist the action of the water indefinitely, are often brought up.

MECHANICAL PROGRESS.

Steel and Steel Castings.

The raw material or the manufacture of wrought-iron and steel, and also for making castings of all kinds, is obtained by the reduction of iron ores in the blast furnaces, and is handled under the name of pig-iron, which varies greatly in chemical composition, according to the purpose for which it is intended. Wrought-iron is the refined iron from the pig-iron that does not occur in a fluid condition. Steel is the refined metal obtained in a liquid condition and can be cast in molds, and has one advantage over wrought-iron by containing a very small amount of oxide of iron and slag. The microscope shows these two deteriorating impurities in large proportions, forming a mechanical mixture with the refined iron. Malleable iron is the same inevitable pig of the required chemical composition which is first cast in molds and the castings heated in an oxidizing material that eliminates the excess of carbon that is always found in pig-iron and renders it malleable. It is a matter of controversy whether or not steel was known to the ancients; in our own period it dates back only a hundred years, and Sheffield, Eng., the home of tool-steel, enjoys the distinction of location.

The manufacturer of good crucible steel, although largely dependent on manipulation, is due to the material used in it; in other words, good crucible steel cannot be made from inferior material. For this best tool-steel the best material is required, and so far none has been found to approach the celebrated brands of Swedish ores for this purpose. By far the greater part of the cost entering any tool is what is paid for labor, and in view of the many mishaps likely to occur, even under the most favorable conditions the best steel should be used, as it is the most economical in the end, notwithstanding a comparatively slight advance in its cost.

Manufacture of Steel Castings.

At the recent meeting of the American Institute of Mining Engineers, at Chattanooga, Tenn., Mr. Pedro G. Salom, of Tburlow, Pa., read some notes on the manufacture of steel castings, stating some of the difficulties encountered in the work. Although castings were made of steel ten years ago, there are only six establishments now in the United States engaged in their manufacture, and these are probably not 10,000 tons produced each year.

Comparing the three processes, the crucible, the Bessemer and the open hearth, he declared the first could never be successful except for making hard and brittle castings, the result being full of blow-holes or the fluid metal being too pasty to run into the molds. By increasing silicon to from one-half to one per cent, a perfectly solid casting soft enough to machine well can be obtained; but it has lost all ductility, though with a tensile strength of 50,000 pounds and not as brittle as pig metal.

Bessemer castings are less homogeneous and higher in carbon than those produced from open hearth steel. Some very solid cranks of Bessemer steel, though perfect in appearance, all broke in half when an attempt was made to shrink them upon the shafts. But open-hearth cranks made at Chester were easily shrunk, and are now in excellent condition after four years' use. Mr. Salom predicts, however, that all castings required for this and similar purposes will eventually be made of Bessemer steel, with improvements in the present mode of manufacture. An exceedingly interesting discovery announced by Mr. Salom is that, other things equal, each 100th per cent of carbon added to the steel increases the tensile strength of the castings by, approximately, 1000 pounds.

Alloys of Iron.

The alloys that can be formed with iron are numerous. Silicon, sulphur, and phosphorus alloys with it in any proportion; tin, zinc and carbon in limited quantities, and silver and lead will scarcely alloy at all. In the chemical properties and combinations, much depends on the process of manufacture. The external and physical disturbances brought about by the rolling, hammering, hardening and annealing under various temperatures and conditions, not only give a variety of chemical compounds, but a material that must differ wonderfully in its molecular structure.

The effects of carbon, a very simple element, reverts entirely on its treatment and chemical condition when it is to combine with iron to form steel. It has at least two distinct forms in its mechanical mixture with refined iron. How many changes it assumes in its chemical condition is very doubtful. In its combined state it is well known to exist in two distinct forms, one a hardening condition and the other a cementing effect. In its cementing state it is entirely dissolved in the metal, but when heated to a red heat and rapidly cooled in water, a portion of the carbon in its cementing state is converted into its hardening form. Simply hammering cold has the same effect to some extent. In the process of annealing the carbon has only to assume its cementing influence. At any rate, the amount of total carbon has but little to do with its physical influence in the behavior of steel.

MATERIALS FOR COLUMNS.—From experiments performed by Prof. Bauschinger, of Munich, it

was found that of all the materials used in columns for supporting portions of buildings, cast-iron and cement concrete best endured the test of great heat, as in fires and sudden cooling with water. Wrought-iron columns failed much more quickly. Brick pillars showed great resistance, but granite, limestones, and sandstone were not fireproof.

Notes on Cast-Iron.

Cast-iron is stronger in compression than wrought-iron, but much weaker in tension. Not so safe as wrought-iron when subjected to impact or suddenly applied loads.

If thickness of different parts varies much the castings will be strained in cooling. All edges should be well rounded and hollows filleted. Expands at moment of solidification in casting, but contracts in cooling. Contraction varies with size and thickness of casting and quality of metal. One-eighth inch per square foot is generally allowed in small patterns for shrinkage.

Chilled cast-iron is ordinary cast-iron rapidly cooled during solidification, by using a solid cast iron mold protected by a wash of loam, causing a chemical combination of the molten iron and carbon. Very hard. Fracture, silvery. Direction of crystallization strongly marked.

Malleable cast-iron is made by heating ordinary castings from two to 40 hours, according to size, in contact with oxides of iron or powdered red hematite, causing partial conversion into wrought-iron by abstraction of carbon.

Toughened cast-iron.—Toughened cast-iron is produced by adding to the cast-iron, and melting amongst it, from one-fourth to one-seventh of its weight of wrought-iron scrap, which removes some of the carbon from this cast-iron and causes an approximation to steel.

Fah.
Melting point of cast-iron 2750°
Melting point of wrought-iron 3250°
Melting point of steel 3250°

UTILIZING THE MECHANICAL ENERGY OF NATURAL GAS.—Ever since the tapping of the first natural gas well in the Pittsburgh districts the question of how to profitably utilize these energies stored up in this fuel has been kept prominently in view. Not the least important of these was the mechanical energy—the gas issuing from some of the wells at comparatively high pressures, ranging from about 65 to 70 pounds per square inch. In some places the gas was accordingly used to drive engines, the pressure only being utilized and the heating power wasted. Where, however, the gas was carried through pipes for long distances, branch pipes running out at numerous points, the pressure was found to be so greatly reduced as to make this impossible, and as the gas, moreover, carried along and other mechanical impurities, its direct utilization in engine cylinders proved of questionable value and often resulted in the necessity for extensive repairs. Practically, therefore, this plan was of little value and but few benefits were realized from it. Notwithstanding this fact, however, it again came to the surface a short time ago and was spoken of in several papers as entirely novel and well calculated to secure exceptional advantages in point of economy and convenience. Obviously this is all wrong, and careful examination of the history of natural gas and its applications would have shown that the method never advanced much beyond the experimental stage.

JAPANESE CASTINGS.—The Japanese are known to be skilled casters of metals. In the Vienna Exhibition there was a casting representing a peacock with drooping and unspread tail, many of the feathers and their bars presenting the appearance of reality, so delicately were they produced. The Japanese employ more time and labor in perfecting metal-work than the workmen in any other country. They appear to understand the art of blending colors in metal work. While giving to metal-work the most artistic finish, they carefully avoid anything approaching glitter, considering that as beautiful effects can be worked out upon common metals as upon gold and silver. Two of the largest castings in this world are to be seen at Nara and Kamakura, Japan; the one at the latter place is 47 feet high and the other, at Nara, is 53½ feet from the base to the crown of its head. The statue at Nara was supposed to have been erected in the eighth century, but it was destroyed and recast about 700 years since. In endeavoring to recast it several mishaps occurred, and when at last success came, some few thousand tons of charcoal had been used. It is estimated that the casting weighs about 450 tons, and that the alloy is made up of iron, gold, tin and copper.—*Mechanical World.*

A GERMAN MODIFICATION of the Bessemer process is being worked out at the new steel works of the Lillshall Company, in Shropshire, of which the Earl Granville is the leading proprietor. An excellent metal is being produced, and it has been rolled into plates for Galloway-tube boiler making and into plates, angles and other engineering sections to the order of such engineering firms as Sir W. G. Armstrong, Mitchell & Co. The basic material of the Staffordshire Company is also being built into boilers by some of the Lancashire and Yorkshire engineers.

Passing Events.

There is little new to note in the general mining situation. The abundant rains have given water to start up the mills with water-power in several sections; in other regions the booming water courses have done more or less damage to miners' works.

It is to be noted that they will shortly start up the lixiviation process at the Lake valley mines, New Mexico, on the Russell system. The process seems to have been successful in Utah, and possibly it will bring about a revival of New Mexican interests, when at work in that Territory.

Recent advices from Alaska show that considerable prospecting for gold is going on in that remote region. If reports are to be believed, some pretty rich diggings have been found along the rivers. There is a vast amount of territory to be prospected, but there are few settlements, and means of travel are not such as to encourage any but the most adventurous to start out. Moreover, the winters are long, and there are many months when mining cannot be carried on.

A NECESSITY TO THE MINER.—An appreciative reader of the PRESS, in Trinity county, writes: "I have recently adopted quartz mining as a business, and very recently became acquainted with the MINING AND SCIENTIFIC PRESS, which I regard as a necessity to the miner and prospector."

New Metallurgical Apparatus.

Joshua E. Clayton and Simon F. Mackie, of Salt Lake City, have patented through the MINING AND SCIENTIFIC PRESS Patent Agency, an invention, the object of which, as respects its primary features, is as follows: To effect a combination of the following known and existing metallurgical apparatus, to wit, a roasting or heating furnace of suitable construction, with a containing vessel or chamber supplied with suitable tuyeres, for the purpose of introducing into the contained mass of material air, steam, or other gases or vapors, at such pressures as will suffice to enable them to boil or be blown through said mass.

In employing this metallurgical apparatus, which they have patented, the inventors charge, through the ordinary forms of feeding gear, the pulp ore or substances to be treated into the rotating furnace, and this being revolved the ore passes down through it, and coming in contact with the flame from the fire-box or other warm gases or vapors generated, is heated or roasted to any desired extent, and in such heated condition empties from the mouth of the rotator into a receiving chamber.

When this receiving chamber (or hopper) is sufficiently full of pulp or roast, air or steam, or any desirable gas or vapor at a suitable pressure is let into the pipes, and passes into one of the cones (the receiving chamber being formed of three truncated cones), where it is slightly heated by contact with the walls, which are surrounded by hot pulp or roast, and thence through tuyeres into the chamber, huddling or boiling up through the material contained therein, until it escapes into a chamber covering the receiving chamber or hopper, whence it passes out through the rotator.

The air, steam or gas, when it leaves the chamber and enters the chamber into which the furnace discharges, has the same temperature as the hot pulp or material in it, and in its passage through the rotator imparts its heat to the cooler material which is fed into it. A discharge wheel below is put in action as soon as the chamber is full and draws off the roast or pulp from the chamber continuously, so that by regulating the feed and discharge the level of the pulp or roast is maintained at any desired height in the chamber.

Dampers admit of regulating the amount of flame which passes into the rotator, and the heat contained therein is thus controlled independent of any regulation of the fire; hence, a hot fire can be used in the fire-box solely for the purpose of heating the superheater, while none or any desired portion of this heat is allowed to pass into the rotator. The supply of air for oxidizing or roasting in the rotator, or for burning any inflammable products which may be generated in the converter, is introduced under the flame from the fire-box, through a main and pipes, and being cooler and heavier than the flame, tends to remain below it in contact with the pulp or roast in the chamber and rotator, and burn or oxidize the escaping gas or pulp. By making suitable pipe connections with the discharge pipes of the superheater they can pass through the superheater and heat either blast which is introduced into the cone, thence out through the tuyeres into the receiving chamber, or the current of air which passes through the main and discharge pipes over the mass in the chamber into the rotator, and by using one or more superheaters they can heat more than one of these blasts or currents.

Lastly, if they choose, the inventors can use certain pipes connected with the tuyeres to introduce into the chamber or rotator, gases other than air; or by using more than one of the pipes and employing one to introduce one gas or vapor, while the other introduces a different gas or vapor, they can blow into the chamber any desired mixture of gases or vapors.

The skilled metallurgist would see that such a form of apparatus would be advantageously used for a great variety of metallurgical operations not necessary to mention here: hence, it will be apparent that the converter may in most cases, not only suffice to accomplish a desired chemical reaction, but will also prove a generator of heat, which could be utilized in the rotator. Of course, modifications of the mechanism can be made. For example: the furnace, instead of being a rotator, as described, might be a stack roasting-furnace, like the Stetefeldt or Gerstenhoffer types, or ordinary rever-

beratory roasting or heating furnaces or an ordinary roasting kiln.

The Weight of Stamps in Quartz Batteries.

Of later years we see a growing tendency to increase the weight of stamps for reducing ores of gold, silver and copper. What is the weight that gives the greatest result for power exerted, is, with the mass of quartz men at this time, an unsettled question. We find some advocating stamps ranging from 750 to 1000 pounds, while others, and these are the older and more experienced quartz men, are more favorable to the lighter stamps and quicker blow, rather than the heavier, which necessitates a less drop and fewer blows per minute. In conversation a few days ago with an old Grass Valley miner, we were informed that in 1851 this same question which we now bring up was the matter of careful and expensive experiment by the Grass Valley and Nevada quartz miners, stamps being used ranging from 400 pounds each up to 1400, varying 100 pounds as the weight was advanced. After careful, practical tests, it was considered that stamps ranging between 500 and 600 pounds, according to one making 80 drops per minute, gave the best result for power exerted, and as all will, remember, for 25 years or more, 600 pounds was the weight of stamps in all first-class batteries. It is only in the past few years that there has been a tendency to increase the weight. Experienced men are of the opinion that our quartz millers are drifting into an expense in this increase of weight, that is not justified by careful investigation as to results, when power is considered. Nearly every mill nowadays has a rock breaker, which first reduces the ore to, say, three-fourths of an inch in size, and thus it is passed to the batteries. A 750 or 1000-pound stamp reduces this—there is no question about that—but the question comes, will not 500 or 600-pound stamps do the same work? Another point: the lighter the stamp the more drops can be had. Then comes the question is there not more to be gained by lighter stamps and more drops per minute? We call the attention of quartz men to the subject that there may be some expression as to what weight gives the best results for horse power. We should be glad to receive communications from millmen on this subject, as to what their experience has been.

A Strong Cable Combination.

We understand that a combination has been formed between the Hallidie and Root cable railway patents in favor of the National Cable Railway Company. This company, the headquarters of which is in New York City, will have these patents for all territory east of the Rocky mountains. These patents, over 60 in number, cover all successful devices that have been used in the construction of all the cable railways of this city, and as A. S. Hallidie and associates put in operation the first street cable railway in the world, it appears to us that it will be rather a difficult matter for any road of this character to be run without the use of the patents owned by the National Cable Railway Company and Mr. Root. The latter gentleman is a practical engineer, and, having superintended the construction of two of the best cable roads in this city—the California street and the Market street—has devised and patented many improvements in the cable railway system, so that the roads here are about as near perfection as it is possible to make them. It was only a few days ago that a party of gentlemen who were here on a visit from New York were making an examination of the Sutter Street cable road, when, after passing over the road and examining the machinery at the station, one of them exclaimed: "Why, in the name of heaven, are we so far behind in this splendid street service in New York? It is perfection, and ought to be worth millions there."

CANES made from California woods, especially of orange, lemon and manzanita, are in heavy demand in the East, and the local manufacturers are doing a very profitable business. The demand comes more generally for light walking sticks, which are sold to small dealers at from \$4 to \$6 a dozen.

THE steamship *Idaho* brought \$70,000 in gold dust from Douglas Island, Alaska, the product of the big mill.

Feeding Ore to Rolls.

A short time since we gave a description of a machine for crushing ore, consisting of cylinders or rolls which rotate toward each other, which was invented by Wm. E. Wild, of this city. Mr. Wild has now obtained another patent through the MINING AND SCIENTIFIC PRESS Patent Agency for a means of feeding ore to the cylinders and preventing waste.

In the present invention the cylinders or rolls are made in the usual way, with gears to rotate them. Around the outside of these rolls, are fitted cylindrical sheets of steel, which serve as shoes to crush the ore passing between them, their faces rotating as nearly together as may be required for the purpose. In order to feed the material to be crushed to these cylinders, a hopper is employed which is composed of two ends, properly supported from the framework of the machine so as to stand vertically at the ends of the cylinders and extend down with their concave lower edges approaching the curves of the exteriors of the cylinders where they run together. These two ends are held together by a strong transverse bar or brace, which extends between them and above the point where the rollers approach each other.

In order to prevent the material escaping between the ends of the rollers and the ends of the hopper, adjustable plates are fitted in openings which are formed on the lower parts of these ends, and these plates may be moved inward, so as to fit closely against the moving ends of the rolls near their peripheries. These plates are shaped with the edges which fit against the rolls made concave, or with curves having the same radius as that of the rolls. These plates are cored out in the center, so that only the outer edges approach the ends of the rolls, and this reduces the amount of wear to a minimum. These plates are set up from time to time, to prevent the material which is to be crushed from sifting out and escaping at the ends.

The November Rain.

The November rains of 1885 being so exceptional in amount, and therefore of great interest, we have obtained from Sergt. Gorum, of the U. S. Signal Office in S. F., a table giving the temperature and rainfall at all the Pacific Coast stations for the month. In the table the temperature is given at the nearest whole degree, and the rainfall is in inches and the nearest tenth of an inch:

Mean Temperature and Rainfall, Nov. 1885.

Station.	Mean Temperature	Rainfall.
Tatoosh Island.....	48	19.2
Olympia.....	46	10.2
Pt. Cauby.....	49	13.7
Portland.....	47	8.5
Spokane Falls.....	41	4.2
Boise City.....	46	2.1
Winnemucca.....	42	3.8
Red Bluff.....	53	17.0
Sacramento.....	54	11.3
San Francisco.....	57	11.8

Los Angeles.....	59	5.5
San Diego.....	58	1.6
Keeler.....	52	0.6
Yuma.....	63	1.7
Salt Lake City.....	44	3.1

MINERS AND PROSPECTORS who do not care to go to the expense of purchasing air compressors and rock drills, but who wish to do rapid work, will do well to examine into the merits of the California Hand Rock Drill. The machine is light and durable, and at the same time effective. The advertisement in another column gives some particulars concerning the machine.

MEMORIAL.—We shall publish next week the memorial delivered by Rev. J. C. Eastman, on the late A. C. Knox, who was for upwards of 20 years connected with the firm of Dewey & Co., publishers of the PRESS.

THE Hecla Consolidated Mining Company of Montana paid a dividend of \$15,000 on the 1st, making \$165,000 for this year to date, or \$912,500 since the start. The stockholders appear to be satisfied.

SIX-TENTHS of the gold product is yielded along with silver, and the demonetization of the white metal would not only discourage the industry of its mining, but that of the yellow metal as well.

NEWS from the Cassiar gold fields say the hill diggings struck on Dease creek give \$14 to a pan of earth.

Lead Smelting—No. 1.

Although a very large amount of technical data on the various smelting works of the West was collected by the census experts, they were not found sufficiently complete to serve as the sole basis for a detailed description of the processes employed. At Leadville, however, where numerous smelting establishments produce annually about \$15,000,000 worth of argentiferous lead bullion, metallurgists have necessarily acquired an unusual amount of practical experience in lead smelting. A succinct account of the natural and economical conditions of smelting at this point, of the character of the plant, and of the processes employed, will be found of general interest. For this purpose recourse has been had to a report by Mr. A. Gnyard, on the lead smelting of Leadville, which is to appear in the census reports as an appendix to a monograph on the geology and mining industry of that district. An abstract of that report has been made by Mr. W. F. Hillebrand, and is supplemented by data obtained from census material by himself and Mr. S. F. Emmons, which appear in the following descriptions. An important condition in the disposition of smelting works, as well as of other reduction works, is that the force of gravity may be used as an aid in handling the material to be treated, which is usually of a bulky nature. To such a disposition the surface character of the Leadville region is admirably suited by nature.

Disposition of the Plant.

No less than sixteen smelting works have been built at Leadville in the few years that have elapsed since its mines were opened. Of these, however, a number have been closed, some temporarily, others permanently. The general plan in these works is that adopted elsewhere, and involves the occupation of two principal floors. The lower of these floors is at such a height above the adjoining valley bottom as to afford a convenient opportunity for dumping slag and other waste. On this floor the furnaces are built, and room is also commonly provided for the blower and the engine by which it is actuated. The furnaces are usually placed in a row within a single inclosure, but sometimes they have a wall intervening between them. The upper floor is on a level with the feeding-door of the furnaces, from 12 to 14 feet above the lower, and affords space for ore-bins, fluxes, mixing-beds, and the operations connected with charging the furnaces, such as crushing and sampling. When the slope of the ground is great, however, the storage bins for ore and fuel are sometimes placed at a still higher level, with passages for wagons between. One roof generally covers the whole establishment, with the exception of the offices, laboratory, and scales, which commonly occupy detached buildings.

Furnaces.

Shaft furnaces only are employed in Leadville. Of these two varieties were in use during the census year, the one presenting

circular horizontal cross-section, sometimes called the Piltz furnace, while the other is rectangular; but in 1882 the latter had entirely replaced the former. While the circular section presents advantages in the regularity of the descent of the charges, it is more expensive in construction, and the diameter of the hearth is limited by the strength of the blast; indeed, with any ordinary blowing-engine a round furnace can be successfully worked only when it is of very moderate dimensions. The rectangular or Raschette furnace, on the other hand, may be constructed with a width at the tuyeres corresponding to the strength of the blast-engines,

ity being from 15 to 40 tons in twenty-four hours.

Fig. 1, represents a rectangular furnace in elevation drawn to a scale of 6 feet to the inch, and Fig. 2, the same furnace in horizontal section at the tuyere level. Fig. 3 shows a vertical section of the same furnace on its longer diameter, and Fig. 4 a horizontal section at the charging-doors. The masonry shaft *C* rests upon a cast-iron plate *O*, supported by pillars *P*, in order that there may be no unnecessary weight on the lower portion of the furnace. The walls for some distance above and below the tuyeres are formed of sectional water-jackets *B*, con-

detail, according to the working of the furnace and the judgment of the manager or smelter, changes in it involving no modification of the iron plates.

The hearth plates include also the lead well *L* and the so-called "siphon tap". A similar device was long ago applied to the small charcoal-iron blast-furnaces of Silesia, to permit of the manufacture of castings without tapping the furnaces; it was not successful, however, the iron chilling too rapidly for the object in view, owing to its high melting point. This arrangement was introduced into lead smelting in Eureka, Nevada, by Mr. Albert Arents with great success, and has since been widely adopted both in this country and abroad. The lead rises through the oblique tap-hole *L* shown in Fig. 1 to the same level in the well which it occupied in the furnace, and can be bled into the molds at leisure, and without the disturbance of the furnace-working incident to the old method of tapping at long intervals.

At the end of the furnace just above the hearth an opening *V* is left in the water-jacket to facilitate the tapping of slag. This opening is filled with clay, in which a hole can be pierced when required, allowing the slag to pass through an inclined gutter *U*, shown in the illustrations, into a slag-buggy. A hood *W* is generally placed over the tapping-hole to draw off the fumes emitted during the tapping. The number of tuyeres varies with the size of the furnace, depending mainly on the length of the cross-section. A tuyere is always placed at the end of the furnace opposite the slag-tap and sometimes also above it; this last, however, is somewhat in the way, and is often omitted. A sliding valve *l* at the elbow of the nozzle admits of the inspection of the interior of the furnace. The tuyeres are connected with the main blast-pipe *I* by canvas hose *K*, the flexibility of which permits their withdrawal from the furnace when necessary. This convenient device is, of course, applicable only when cold air is supplied to the furnace, as is almost invariably the case in lead smelting. Feed-openings *H* on the upper floor are closed by sliding doors *S*. The furnace terminates upward in a short chimney *E* and may, in case of need, be run without the dust-chambers, with which it is connected by a flume *F*, indicated in the illustration.

As an example of recent construction, the furnaces in the works of Eddy, James & Grant, at Denver, may be cited. There are eight of these furnaces of the same pattern, all built in the spring of 1882. The height to the charging-door is 18 feet; the dimensions 3 feet below the charging-door are 60 by 102 inches; at the top of the jackets, 48 by 92½ inches, and at the tuyere level, 36 by 80½ inches. Each furnace has ten tuyeres, four on each side and one at each end. The capacity of each is about 30 tons. The waste gases and fumes are drawn from all these furnaces at a point below the charging-doors into large dust-chambers connecting with a single stack—a very convenient arrangement so far as the comfort of the workmen is concerned; whether it is accompanied by any ill effect upon the working of the ore is regarded as uncertain, but each furnace is provided with an independent stack, to be used in the event of its proving desirable to return to the ordinary practice.

CABLE RAILROAD SYSTEMS.—We see by the Philadelphia papers that A. H. Lighthall, of this city, is organizing there a new street cable company, to run in opposition to the Philadelphia Traction Company. According to the Philadelphia Times, Mr. Lighthall is "patentee of the San Francisco system, and owns and controls a complete system of patents for the traction of street tram-cars by means of one endless cable." Part of this is news to San Francisco people, for the gentleman is not the patentee of any system in use here. He has several patents of his own on a system of cable roads, but as far as we know they have not been practically tried. At all events the Lighthall system is not in use in this city. The Philadelphia people have already paid dearly for trying new experiments in cable roads, and it would perhaps be just as well, in case they build new ones, to adopt the system which has stood the test of experience for years. Mr. Lighthall's only connection with cable roads here, as far as we are informed, was when he was engineer for a short time on a block and half extension of the Larkin street branch of the Sutter street railroad. Some of his devices may have been applied here, but as to a complete system, it is a mistake,

RECTANGULAR FURNACES FOR LEAD SMELTING IN USE AT LEADVILLE, COL.

and the production may be increased by increasing the length of the cross-section. The horizontal elongation of the furnace has its limits, indeed, as has been proved by the history of the rectangular Raschette furnaces in Europe, but the capacity may nevertheless be increased considerably above that of a circular furnace of similar construction without deleterious effects upon the working. In lead smelting, and especially in smelting argentiferous lead ores, it is very undesirable to employ the high-pressure blasts required by a circular furnace of large diameter, since the higher temperatures which result promote the production of fumes which are only imperfectly recovered and are always difficult of treatment.

The rectangular and the round furnaces of Leadville are constructed on the same general plan so far as height, method of support, water-jackets, tuyeres, etc., are concerned, but the sizes adopted vary greatly, the limits of capac-

ity being from 15 to 40 tons in twenty-four hours. The furnace illustrated the water-jackets are twelve in number, firmly bolted together and provided with openings for the insertion of the tuyeres *N*. A cold water pipe *M* runs around the furnace above the water-jackets, and water is admitted to each of them by a faucet *Y*. Outlets *M'* for the hot water and gutters *T* for its removal are also shown in the illustrations. The interval *b* between the water-jackets and the plate on which the shaft of the furnace rests is filled with fire-brick, which can be readily removed in case of necessity. The lower ends of the water-jacket rest upon the hearth *X*. This consists of cast-iron plates *a* bolted together and lined with a thick coating of fire-brick, or of "steep" (brasque), a mixture of fire-clay and coke-dust, either in equal parts, or in the proportion of two of the former to one of the latter. The usual form of the hearth is shown in the illustrations; this, however, is modified in

PRACTICAL HYDRAULICS.

NUMBER 8.

PRINCIPLES OF HYDRAULICS.

[Written for MINING AND SCIENTIFIC PRESS by P. M. RANDALL.]

[COPYRIGHTED.]

FLOW OF WATER THROUGH VERTICAL, RECTANGULAR ORIFICES IN THIN PARTITIONS.

The assumption that the mean velocity of a stream of water flowing through a vertical rectangular orifice is at the middle of the opening, has been shown by equation (22) to be not strictly true. But, owing to its simplicity of application, and its close approximation to the truth, hydraulicians, for the most part, are wont to adopt it, and to correct the error involved by coefficients obtained by experiment.

Table 7, derived from Fanning's Hydraulic Engineering, embraces a wide range of coefficients so determined. Thus, it is suited to heads of water from two-tenths (.2) of a foot to fifty (50) feet, and to orifices one foot wide, whose heights vary from four (4) feet to one and one-half (1½) inches.

An inspection of Table 7 discloses that the coefficient of flow is variable, both with respect to the head of water and form of orifice.

Thus, the orifice being "four feet high," the maximum coefficient .629, is due a head of 2.50 feet; thence the coefficient gradually diminishes to .604, as the head increases to 10 feet; thence is constant to 15 feet; thence gradually increases to .609, with the increase of the head to 50 feet.

In the other given orifices, variations obtain, but to a less extent.

With respect to the variation of coefficients arising from the form of orifice, it will be seen, by running the eye horizontally to the right, from and for any given head, that the values of the coefficients diminish as the heights of the orifices decrease from four feet to one foot, and increase as the heights of the orifice decrease from one foot to one and one-half (1½) inches. In illustration take several heads, as 3, 10, 25, 50 feet, and the coefficients due the several forms of orifice.

Head, Feet.	4' x 1' Coef.	2' x 1' Coef.	1½' x 1' Coef.	1' x 1' Coef.	9" x 1' Coef.	6" x 1' Coef.	3" x 1' Coef.	1½" x 1' Coef.

TO FIND THE FLOW OF WATER IN CUBIC FEET PER SECOND THROUGH VERTICAL RECTANGULAR ORIFICES IN THIN VERTICAL PARTITIONS BY TABLE 7, THE HEAD ON CENTER AND SIZE OF OPENING BEING MADE.

Rule 26.—In "head on center" column, Table 7, find the given head, opposite which, in column headed by the given height of orifice, will be found the flow for an orifice one foot wide, which multiply by the given width in feet.

Ex. 40.—The head being ten feet, and orifice four feet wide and nine inches high, what is the flow per second?

Cal.—In column "9" high 1 foot wide," opposite 10 feet in "head on center" column, will be found 11.44 cubic feet, which, multiplied by four feet, the given width, gives:

$$11.44 \times 4 = 45.76 \text{ cubic feet.} \text{—Ans.}$$

The heads, sizes of orifices, and the computed flow of water given in Table 7, will be found highly convenient for ready reference in a great number of cases, but are seen to be too limited to fully meet the requirements of practice. Indeed, a table sufficiently ample for that purpose would be too unwieldy for use.

The general formula for the flow of water per second through vertical rectangular orifices in thin partitions, is:

$$Q = 8.025ca\sqrt{h} \quad (92)$$

In which Q denotes the flow in cubic feet; c , coefficient of discharge; a , the area of the orifice in square feet; and h , the head on the center of the orifice; h' is equal to the half sum of the respective heads on the bottom and top of the orifice, as seen in equation (21).

In case the height of the orifice and the head on its top are given, then h' to the sum of the given head and half the height of the opening; or if the height of the opening and the head on its bottom are given, then h' is equal to the difference between the given head and half the height of the orifice.

TO FIND THE FLOW OF WATER IN CUBIC FEET PER SECOND, THROUGH VERTICAL RECTANGULAR ORIFICES IN THIN PARTITIONS.

Rule 27.—Multiply 8.025 times the square root of the head on the center of the orifice, by the product of the area of the orifice and the coefficient of discharge.

Rule 27 corresponds to formula (92).

With respect to the "square root of the head," and "the coefficient of discharge," contemplated in Rule 27, it will be remembered that Table 6 gives the square roots of numbers likely to be required, and Table 7, the coefficients of discharge. In finding a proper coefficient of discharge: in case the given height of orifice is found in Table 7, the coefficient corresponding to that height and to the given head is to be employed; but in case the given height of orifice is an intermediate, or lies between the heights contained in the table, its coefficient will need be computed. The tabulated coefficients are, in fact, ordinates of curves, determined by experiment.

In determining these intermediate ordinates or coefficients between any two adjacent heights in Table 7, as 4 feet and 2 feet, 1.5 feet and 1 foot, no appreciable error will occur by substituting a right line for a curve. The determination of the intermediate coefficients will then be effected by arithmetical differences. In illustration, let it be required to find the coefficient due a head of 2.5 feet, and orifice 3.5 feet high.

Now 3.5 is between the adjacent heights, 4 and 2 feet, in Table 7. The respective coefficients due a head of 2.5 feet are .629 in "4 feet high" column, and .618 in "2 feet high" column.

Difference of heights, $4 - 2 = 2$ feet.
Difference of greater and given heights, $4 - 3.5 = .5$ feet.
Quotient of these differences, $.5 \div 2 = .25 = 4$ divisor.
Difference of coefficients, $.629 - .618 = .011$
Arithmetical difference sought, $.011 \div 4 = .003$ nearly.
Coefficient due 3.5 feet, $.629 - .003 = .626$

The intermediate coefficients corresponding to 3 feet and 2.5 feet are now readily found. Thus:

Coefficient due 3 feet, $.626 - .003 = .623$
Coefficient due 2.5 feet, $.623 - .003 = .620$

EXAMPLES AND CALCULATIONS.

Ex. 41.—An orifice is 3.5 feet wide, 1.25 feet high, and the head on its center is 7 feet. What is the flow in cubic feet per second?

Cal.—By Table 6, square root of 7 feet = 2.646.
By Table 7, coefficient due 7 feet; for orifice, 1.5 feet high = .604; for orifice, 1 foot high = .601.

Difference of tabulated heights, $1.5 - 1 = .5$
Difference of greater and given heights, $1.5 - 1.25 = .25$
Quotient of these differences, $.25 \div .5 = .5 = 2$ divisor.
Difference of coefficients, $.604 - .601 = .003$
Arithmetical difference, $.003 \div 2 = .0015$
Coefficient due 1.25 feet, $.604 - .0015 = .6025$

Area of orifice, $3.5 \times 1.25 = 4.375$ square feet.

Flow = $8.025 \times .6025 \times 4.375 \times 2.646 = 55.97$ cubic feet.—Ans.

Ex. 42.—Given the head on the bottom of a rectangular orifice 12 feet, the head on its top 11 feet, and the width of orifice 4 feet, what is the flow in cubic feet per second?

Cal.—Head on center = $\frac{12+11}{2} = 11.5$ feet.

By Table 6, square root of head on center = 3.391 feet.

Height of orifice = $12 - 11 = 1$ foot.

By Table 7, coefficient due head of 11.5 feet, and orifice 1 foot high = .601.

It will be observed that the coefficient is constant for head from 10 to 15 feet, inclusive.

Area of orifice = $4 \times 1 = 4$ square feet.

Flow = $8.025 \times .601 \times 4 \times 3.391 = 65.42$ cubic feet.—Ans.

Ex. 43.—The head on the top of a rectangular orifice 6 inches high and 6 feet wide, being 7.25 feet, what is the flow in cubic feet per second?

Cal.—Half the height of orifice $6'' \div 2 = 3'' = .25$ feet.

Head on center = $7.25 + .25 = 7.5$ feet.

By Table 7, coefficient due head of 7 feet = .606.

Coefficient due head of 8 feet = .603.

Mean coefficient on that due 7.5 feet = .6045.

By Table 6, square root, 7.5 feet = 2.739.

Area of orifice, $6 \times .5 = 3$ square feet.

Flow = $8.025 \times .6045 \times 3 \times 2.739 = 29.89$ cubic feet.—Ans.

Ex. 44.—The head on the bottom of a rectangular orifice 9 inches high and 3 feet wide, being 15.875 feet, what is the flow in cubic feet per second?

Cal.—Half the height of orifice, $9'' \div 2 = 4.5'' = .375$ feet.

Head on center = $15.875 - .375 = 15.5$ feet.

By Table 7, coefficient due head of 15.875 feet, and orifice 9" high = .601.

Observe that the coefficient is constant from 10 feet to 20 feet, inclusive.

By Table 6, square root of 15.6 = 3.95 feet.

Area of orifice = $3 \times .75 = 2.25$ square feet.

Flow = $8.025 \times .601 \times 2.25 \times 3.95 = 42.86$ cubic feet.—Ans.

The preferable unit for measuring the flow of water is 1 cubic foot, but so widely is the "miner's inch," employed in California as a unit of measure, that we cannot well pass it in silence.

"MINER'S INCH."

The term "miner's inch" is employed to express that quantity of water which, under a given head or pressure, as 4, 7, 9, etc., inches, will flow through each square inch of a discharge opening; or, in other words, which will flow through each square inch of cross section of a stream of water.

The quantity of water so flowing in a minute, an hour, 24 hours, etc., is designated *minute inch*, *hour inch*, *24-hour inch*, etc., according to the length of time specified.

STATUTORY MINER'S INCH.

Under the head, "Water Rights," the Civil Code of the State of California, Sec. 1415, provides in these words, "That he (the locator) claims the water there flowing to the extent of (giving the number) inches, measured under a four-inch pressure."

Death of a Notable Pioneer.

Colonel Peter Donahue, who died in this city last week, was a man who lived a very useful life, and whose work contributed largely to industrial progress on this coast. He was a mechanic who, by his own exertions, became a millionaire. The first manual labor which he performed in the United States was in a cotton factory at Matteawan, where he worked for two years. He then entered the great locomotive manufacturing establishment of Rogers, Ketchum & Grosvenor, in Paterson, N. J., as an apprentice to the millwright and engineering business. At the age of 22 years he entered the foundry of Hugh Biggs, at Paterson, N. J., as a journeyman, and worked there for a year, at the end of which time he returned to the banks of the Hudson and entered the employ of Gouverneur Kimball, whose foundry was situated at Cold Springs, Putnam county, and labored there for two years. New York City was the next scene of his labors, and here he became connected with the Novelty Iron Works, which at that time was the largest establishment of the kind in the United States. Here he most energetically pursued his business until 1847. In December of that year he was appointed assistant engineer on the Peruvian war steamer Rimac. He was also engineer of the first steamship ever owned by the Peruvian Government, and of the first American steamer that ever went through the straits of Magellan. Mr. Donahue arrived in San Francisco on the second trip of the steamship Oregon, in June, 1849. He went to the mine and remained eight months at Auburn, and then went to Kelly's Bar, on the north fork of the American river, where the diggings were then very rich.

After a while, with his bearskin and blanket on his back, he tramped back to Sacramento. Shortly after arriving at the future capital, Mr. Donahue erected a saw-mill on a seow for the Phoenix Company. While erecting the mill he was paid at the rate of \$10 a day and his board.

When his brothers came from the East he joined them in this city, and in connection with his brother James, opened a blacksmith shop and boiler-making establishment on Montgomery street, just above Jackson. Here they did business for about a year and a half, afterwards removing to First street, between Market and Mission, where the Union Iron Works were erected. The Donahues can truly claim that they melted the first cast-iron in California. They also erected the first quartz mill ever built on this coast. Credit is due to the three brothers for having melted and molded the first cast-iron in the State, which was done by means of an antiquated blacksmith bellows.

The first printing press ever manufactured in California, and the one upon which was printed the paper which announced the tidings of the admission of the State into the Union, was manufactured at their foundry.

In 1852 the firm obtained a franchise from the city for the erection of gas works, laying gas pipes and lighting the city. Peter Donahue also started an opposition line of steamers on the Sacramento river, at the same time having two steamships engaged in the coasting trade. In addition to his other works, in 1861 he obtained a franchise for the Omnibus Street Railroad, which is yet in operation. The same year he obtained the contract for the construction of the monitor Comanche for the defense of the Pacific Coast.

In 1862, with a few associates, Mr. Donahue built a railroad from San Francisco to Gilroy, a distance of eighty miles. This road was afterwards sold to Leland Stanford. A broad-gauge road was also built from Donahue, at the mouth of Petaluma creek, to Cloverdale, a distance of fifty miles. All the rolling stock used on this road was built at Donahue's foundry. A branch road was also built from Fulton to Russian river, a distance of eighteen miles, and from Petaluma to San Rafael, twenty-two miles. On the latter road there is a tunnel 1400 feet long through the solid rock. With the approaches the tunnel is 2200 feet long. This latter branch has also been extended from San Rafael to Point Tiburon, on Raccoon straits, connecting with San Francisco by a ferry-boat, this branch of the system costing nearly a million of dollars.

In 1879, the corporation of which Mr. Donahue was the President bought the unfinished narrow-gauge road from Sonoma to Sonoma creek, and finished the road to the mouth of the creek, and then made connection with San Francisco by the steamer James M. Donahue.

From the above brief sketch of his business career on this coast it becomes apparent that Mr. Donahue was eminently entitled to the appellation of Founder. Not content with deriving benefit from and enlarging upon the ideas of others, he has himself given birth to extensive schemes, which his energy coupled with his extraordinary executive ability, has invariably brought to a successful culmination. The first to engineer a steamer through the straits of Magellan; the first to establish an iron foundry and machine shop in San Francisco; the first to introduce gas illumination in this city; the man whose skill and perseverance liberated the San Jose railroad from its enthrallments; the first to construct a street railroad in San Francisco, and the only man in California who ever ventured to build a railroad without the aid of a land grant.

USEFUL INFORMATION.

The Hook of a Chain.

Here is another place where the working mechanic, in trying to forge out a hook for a chain, weakens the material, distorts the fiber, and abuses the strength of the iron by the strains left within the hook when finished. It is the only portion of a chain that must endure the breaking, bending, and stretching tendency of a load in an off-hand disadvantage; every strain must be taken to one side to allow the chain to be unhooked from the other, and has every tendency to disturb the curvature of that graceful reversing curve that forms the back of a hook of a chain. If a hook could be so proportioned that even an expert would find it difficult to decide where it would break first, it might answer for many purposes, but there are places where this theoretical hook would be treacherous. A flattened hook is the stiffest, and where it is left the thinnest in the back edge, gives the most strength for a given amount of material, but it breaks without warning. What a workman needs, where life is in danger, is a hook that will give some indication of being overloaded before it breaks. It is a desirable feature in every structure to have some of the working parts so constructed as to give the workmen notice of an impending break down. The foundrymen with their glowing material, would prefer to see the opening in the hook of their chain spread out a little, for enough to attract attention, than to create a disturbance that would be detrimental to their own welfare by the breaking of a chain. A hook with circular cross-sections can be partially straightened by overloading when the flat hook would show no inclination to spread, and both be on the point of breaking. The difference in their strength is not shown by the opening of their jaws. The only advantage in making the hook flat is to resist the bending and breaking across as if it were a bar loaded at both ends and supported in the middle. But the strain of a hook is in the direction of the length of the chain and the very force that is bending the back and drawing the hook out in a straight line is the very one that is being supported by it, and a round bar is just as well prepared to support a load in the direction of its length as the same amount in cross sections in any other form. It is surprising what a slight difference there is to be seen in round and flat bars when used for a hook than when used for direct bending. Even the flat hook fails when it is made to grasp two links at once with a heavy load on both of them and the second one with no room to spare. The hook is broken where a direct pull had been provided for by the forger. A hook that has the privilege of spreading before it breaks would make room for the links to lie more comfortably. Where the strength in design is but little affected by the form that is given, the very important feature of "bending before it breaks," should not be lost sight of, though a trace of it is found in the hook of a chain.—*Boston Journal of Commerce.*

A NEW ARTICLE OF MANUFACTURE.—The *Denver Journal of Commerce* reports that the slag resulting from the smelting of copper, gold and silver ores at Argo is now being returned in the shape of a beautiful table-ware. The colors are a sort of spray of onyx and opal flushed in waves throughout the ware. The glass works where it is made say they have direct control over these colors, the slag containing a larger per cent of material necessary than can be found in slag elsewhere. It is melted at an intense heat, then poured into vats of agitated water, then remelted and poured into molds after or together with an acid mixture, which causes the metal to flux pretty generally with added materials. The result is a metallic glass with the strength of light cast-iron, and in any form of tableware, bowls, cups, tumblers, etc., with the most beautiful spray of onyx stone colors upon a general background of opal.

TO REMOVE DRY ROT.—A Russian professor has been experimenting on the best way to remove dry rot. He says that a thorough draught will destroy the parasite which produces it in 24 hours. If the action of draught be assisted by sunlight a few hours will often be sufficient to put a stop to further damage. A concentrated solution of common salt is very efficacious, and the stronger it is used the more rapid its action. The action of a concentrated solution of "blue stone" is still more energetic and complete than that of common salt. Crude carbolic acid is rapid in its action and cheap, but inconvenient to use. He considers the best, cheapest and most convenient material to employ is the tar obtained when birch wood is distilled for acetic acid; the under surface of the flooring should be painted with this tar.

A NEW REPEATING RIFLE.—A French officer of infantry has invented a repeating rifle, which is believed to excel everything of the kind hitherto devised. The weapon can be loaded with its seven cartridges in ten seconds and completely discharged in four. A great merit of the arm is that it can be fired until the magazine is exhausted without being removed from the shoulder.

INDIAN SECRETS.—Actual analyses of the secrets of Indians reveal the fact that their mixtures for attracting game to their traps is

easy to make and apply. For foxes and other large game, mix together muskrat and skunk muck in equal parts, smear the trap and bait with this, and the animals will soon "get a foot in." For minks, etc., take unslaked lime, one-half pound; sal ammoniac, three ounces; mix and pulverize, and place in a covered vessel a few days until thoroughly mixed, then sprinkle on the bait and around the place where the traps are set.

WHEATENA is the name given to a new manufactured product from wheat, intended as a breakfast food. It is said to combine all the good qualities claimed for the various cereal preparations of similar character, and some others peculiar to itself. It is manufactured from peeled or hulled wheat, of the best varieties, and so prepared that it can be so perfectly cooked in two minutes, that no additional amount of cooking will in any way improve it. It is said to be digestible, palatable and nutritious.

OPPOSED TO BOYCOTTING.—Manufacturers and others who are being "boycotted" in New York City, are quietly arranging to have a bill presented and pressed for passage at the next session of the New York Legislature, making boycotting a misdemeanor, punishable with heavy penalties. The trades union people have an inkling of the movement, and will make extra exertions to see that only men who will give their interests consideration shall be sent to the Legislature.

ANTIQUITY OF TRADE-MARKS.—The antiquity of trade-marks has been traced by a contemporary to be almost coeval with the industry of the human race. It has been found that ancient Babylon had property symbols, and the Chinese claim that they had trade-marks 1000 years before Christ. Gutenberg, the inventor of printing, won a lawsuit about a trade-mark, and the use of a distinguishing stamp was recognized by the English Parliament in 1300.

GREASE-ERADICATOR.—The constitution of a celebrated grease eradicator, the right to make which has made four millionaires, is as follows: Ammonia, two ounces; soft water, one quart; saltpetre, one teaspoonful; fine soap, in shavings, one ounce; mix thoroughly and keep in covered vessels.

RAT EXTERMINATORS.—The best rat-exteriorator ever examined in a laboratory is simply chlorido of lime. This is thrown liberally about their holes and runways, and they will never sniff it but once.

GOOD HEALTH.

THE PAIN OF BEING HUNG.—Dr. Taylor states that death from hanging appears to take place very rapidly, and without causing any suffering to the person. Prof. Tidy also speaks of the painless nature of death from hanging; while Prof. Houghton, in his paper read before the Surgical Society of Dublin, says that the old system of taking a convict's life by suffocation is inhumanly painful, unnecessarily prolonged, and revolting to those whose duty it is to be present. Those who speak of the painless nature of death by strangulation arrive at this conclusion from the fact that many cases of suicide are not completely suspended, and that if they wished they could easily relieve the constriction by assuming the erect posture; and in other cases of recovery from attempted suicide by hanging there is no recollection of any suffering. It should be remembered, however, that there is a great difference between the mental attitude of the suicide and one who is about to suffer the extreme penalty of the law. In the former case he is regardless and perhaps also not very sensitive of a little suffering, while in the latter every nerve is braced up to resist the inevitable result. Moreover, in those cases of recovery the loss of recollection of suffering does not prove there was none. It might almost as well be said that, because in many cases of recovery from meningitis there was no remembrance of any suffering, therefore there was none. No doubt the pain in hanging can under no circumstances be very acute, yet when we see a culprit heaving his chest and almost raising the whole body in his struggles for breath, we must conclude that there is at least a considerable amount of mental torture.

REMOVING HAIR AND FRECKLES BY ELECTRICITY.—The American Dermatological Association lately held its ninth annual meeting at Greenwich, Conn. Among the proceedings were remarks by various doctors who gave their experience in removing hair from the face by electricity. Quite a large and important business is done in this line, especially among ladies. The only remedy is to kill the root of each hair, which must be done separately, by means of an electrical needle and battery. Dr. Fox said: In the case of a young woman with a heavy beard, he had removed, by actual count, 8000 hairs. This process had required two or three years. Since then it had been necessary to remove only a few dozen hairs. The president, Dr. Hardey, had performed the operation of electrolysis for 10 or 12 years—probably longer than any other member of the association. He used the Iridogalvanic needle, which had the advantage of being bent, and was not likely to pass

through the follicle wall. The moment the follicle was entered there was an escape of serum. One case, that of a woman with a heavy black beard, had been entirely relieved. It is said that electrolysis, with a fine needle, also affords a method of getting rid of freckles. The plan is to dot the surface covered by the freckle with the needle.

HOW CAN TYPHOID FEVER BE PREVENTED?—The reply to the above question may be stated in four words: stop drinking contaminated water. This might not prevent all typhoid fever, but it would by far the greater proportion of it. How to prevent the contamination of the various water supplies cannot be briefly stated, but if people care enough about it to take the necessary trouble to do this, sanitarians can tell them how. So far as it relates to typhoid fever, it may be that all that is necessary is to destroy and keep out of the water all discharges from persons suffering from typhoid fever; but the difficulty of recognizing the disease early enough in its course is so great, that in order to do this it will be necessary to keep all human excreta, and perhaps the excreta of some animals, out of the water supply. Most people think they do this now, or probably we would not have a thousand deaths a year in one State from that cause; but I think we have reason to believe that their confidence in the purity of the water they drink is misplaced. The numerous instances where typhoid fever has apparently been caused by drinking water contaminated by decomposing vegetable matter indicate that even if the cause of the disease is specific, until such time as the specific cause shall be so restricted as not to find access to water supplies, it is important to preserve the water from contamination by vegetable as well as by animal matter.—*Henry B. Baker, M. D.*

FILTERS.—Many people pin their faith to filters, and think that so long as they pass their drinking-water through an earthenware jar with some mysterious filtering medium inside, the source of the water or the condition of the cisterns does not in the least matter. This is a similar delusion to the belief, which passes freely current, that if you add spirits to unwholesome water you rob it of its noxious qualities, or at least diminish them. We do not deny the usefulness of filters, but we desire to point out that they must not be exclusively relied upon. Water filtration has in its way had as much nonsense written about it as water analysis. The great point is to keep the water itself as pure as possible. Where pollution is suspected, let the water be well boiled for a considerable period. It may afterwards be aerated by pouring it several times from a height of two or three feet from one vessel to another, or by artificial means. If a filter be used it should be of the simplest possible construction, and the filtering medium should be readily removable for cleansing purposes. If a filter be not very frequently and very thoroughly cleaned it pollutes rather than purifies the water.—*Herald of Health.*

THE REMEDY FOR OBESITY.—The London *Lancet* does not believe in the propriety, on physiological grounds, of a limitation to a specific class of foods to the exclusion of such as are known to be fat forming. It holds that it is the quantity rather than the quality of food that should be limited, on the ground that the health of the entire system absolutely demands a mixed diet, and that any considerable diminution in the supply of any one of the important forms of nutriment will be likely to produce much more serious consequences than the obesity which it is designed to relieve. As the *Lancet* puts it, "if the requisition of mixed food for the whole body be rudely interfered with, some other function may suffer and become deranged. While, therefore, we are ready to admit that stout persons should be content with a less rich diet than the spare bodied, its mixed character should be carefully preserved. Its quantity should, however, be limited, and we should rely for the disposal of the products of digestion mainly upon regular and methodical physical exertion."

THE TIME TO WEAR GLASSES.—When persons find their eyes becoming dry and itching in reading, as well as those who find it necessary to place an object more than 14 inches from their face to read, they need spectacles. Spectacles sold by peddlers and jewelers generally are hurtful to the eyes of those who read much, as the lenses are made of inferior glass, and are not symmetrically ground. Unless the lenses are mounted in a suitable frame and properly placed before the eye, discomfort will arise from their prolonged use. The proper time to begin wearing glasses is just as soon as the eye tire on being subjected to prolonged use.—*Medical Herald.*

MOUTH-WASHES.—The following mouth-washes are recommended for sick persons, whose teeth and gums often become unhealthy through insufficient nourishment, medicine, or want of cleansing.—One part permanganate of potash to from one hundred and fifty parts of water, to which can be added some camphor, as the metallic taste is disagreeable; or a solution of boracic acid one in twenty or thirty; or the following:—Tincture of benzoin, ten parts; tannic acid, twenty parts; alcohol, thirty parts; oil of peppermint, a sufficiency. Put ten or twenty drops into a glass of water.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ST. JULIAN.—Amador Ledger, Nov. 28: This mine at Middle Bar is being energetically prospected, considering the limited means at the command of the owners. Four men are kept busy running the tunnel on contract at \$3.40 per foot. This tunnel has been advanced 200 feet under the existing contract, making a total length of 300 feet under cover, and 400 including the open cut. It is advancing at the rate of from 12 to 18 feet per week, according to the nature of the rock. Less than 50 feet more, it is believed, will bring it to the point where the heavy gold bearing metal is known to exist. The past record of this claim justifies a thorough prospecting. In one pocket discovered early the present year, the sum of \$6000 was realized. A week's run of a one-stamp mill has panned out \$1500.

MISCELLANEOUS.—James Gleason has charge of the Moore and Mammoth mines in the absence of W. A. Nevills, who is compelled to be away a considerable portion of his time to look after his interests elsewhere. Mr. Rose has charge of the Bechtel mine at Angels. The new air-compressor at the big tunnel at Middle Bar was started this week. It is said to be a splendid piece of machinery, and works to perfection. Reports are current that another bunch of rich black metal was encountered early this week. A small box full of the ore was taken out. This is chiefly encouraging, not so much on account of the amount of gold obtained, but because it disproves the theory that the pockets exist only near the surface, and shows that, like the ordinary gold-bearing quartz of the mother lode, they extend down to unknown depths. It must be remembered that this tunnel enterprise is the only experiment that has yet been made to solve the problem of whether the peculiar ores met with in the Middle Bar group of mines are merely superficial deposits or otherwise. So far the result is sufficiently encouraging.

SUTTER CREEK.—The repairing of the Eureka shaft is being pushed ahead with all possible speed. The largest kind of timbers are being put in, and everything pertaining to the work is of the most substantial and lasting character. As the shaft is nearly 1300 feet deep, it will take all winter to complete the job. T. L. Culbert, of Amador City, has two large teams at work, hauling timbers to complete a contract, but they are coming in very slowly, owing to the terrible condition of the roads. The Mahoney and Lincoln mills are running steadily; also the five stamps of the Iowa. On account of the heavy rains, the miners have been unable to work on the surface ledge at the Mahoney, consequently the mill has almost exhausted the ore on the dump. On visiting the old shaft of the Lincoln, recently, it was discovered that it had caved badly. The cave extends from the surface to probably below the 200-foot level; beyond that the shaft was in good condition. There are two or three pumps in the shaft, which are likely to stay there, as it is not probable that the shaft will ever be used again.

Calaveras.

GREEN MOUNTAIN MINE.—Calaveras Chronicle, Nov. 28: One of the most substantial gravel mines in this district is the Green Mountain mine, located on Tunnel Ridge, and owned by McSorley, Son & Co. The gravel in this mine, it may be said, is almost inexhaustible. The main lead is 600 feet wide and 80 feet high. The company are now, and have for the past eight years been working on the northern extension, which is only an iota of the vast amount yet to be worked. The mine is worked by means of two tunnels, about 300 feet apart, and connected on the inside by drifts which afford ventilation, and insure safety to the men employed therein. The tunnels are run to a distance of 900 feet, first through lava and bedrock, then through a stratum of cemented sand, and cutting through the main lead or channel until the eastern wall or edge is reached. From this point drifts radiate at distances of 60 or 70 feet running north and south; north as far as the Brackett & Boucher line, and south as far as the grade of the channel will permit it to be worked advantageously. The gravel is then breasted or blocked out to a height of 6 feet between these drifts in a skillful and systematic manner, beginning at the further edge so that no gravel is left behind. The rocks encountered are walled up in pillars to prevent caving, and answer the purpose of timbers, but notwithstanding a large amount of the latter are used. The southern extension of the channel, which is about 2000 feet in length, is yet untouched, but in order to be worked with advantage a tunnel will have to be opened to tap the lead at the southern end. This the company intend commencing in the spring, and when completed it will insure years of profitable labor. The gravel is hard and cemented, which requires milling to extract the gold. For this purpose an 8-stamp mill was erected and propelled by water power with a hydraulic pressure of 260 feet, thus requiring but a small amount of water. Twenty men are employed in the mine getting out an average of 70 carloads of gravel daily. For the first three years this mine was worked on the old plan and at least one-third of the gold was lost. But since the erection of the mill, the dividends derived thereby have been more than doubled. No hoisting works or water pumps are required. The tunnels being on a slight grade, the water flows out, and the ears are easily pushed in and out by hand, by which great saving of water and machinery is effected. This mine, like most others, was worked in former years, but the gravel being of such a nature as to require milling to extract the gold, and this process being but little used on those days, it was abandoned after working a strip of 150 feet, which was soft, and easily worked on the east edge of the channel.

Del Norte.

HAPPY CAMP.—Del Norte Record, Nov. 28: Mr. Wilson, who has just returned from Happy Camp, informs us that the mines at that place are all in full blast, except that of Camp & Co., and a successful mining season is expected. Everyone has put their mines in the best possible condition, and now that the rainy season has set in, they have nothing to do but to work and take out the needful. The Waldo

mines are all in operation, and will, in all probability continue to be so all winter. Wimer & Sons are jubilant over the prospect of a good winter's run and a big cleanup in the spring.

El Dorado.

PAYING.—Georgetown Gazette, Nov. 28: Supt. Dixon of the Revenge mine and mill, Greenwood district, was up on a business trip last Monday. We are pleased to learn that the Revenge continues to yield its golden treasure in paying quantities. We are pleased to learn that Henry Jones and A. E. Brass who have been prospecting for the past few months on the Slate Mountain lode to the north of the Slate Mountain mine have developed a fine body of gold bearing quartz which they believe will equal in richness the now famous Slate Mountain mine.

Inyo.

WILL HANG UP.—Register, Nov. 28: For lack of sufficient ore to keep the mill supplied to a paying standard on custom work, John Alexander will soon give up his lease of the Maxim mill. He has run it successfully as regards making the many different lots of ore pay that he has worked, but the different lots have been small for the most part, and the supply too irregular to justify himself.

UNOVELOPEO RESOURCES.—Independent, Nov. 28: In the low range of hills that runs across the valley fifteen miles north of Independence, is a large bed of kaolin. This is the material of which the finest porcelain wares are made. Parties have been making investigation lately to determine the quantity and extent of the deposit. Very large establishments have grown up in France and Germany where similar material is found. At Chrysopolis, across the river east from the above, is a large bed of soapstone. This has been tried to a limited extent and found far superior to the best imported English fire brick for use in furnaces. Near Cerro Gordo are other beds of soapstone from which blocks have been taken for furnace use, and were found to answer the purpose perfectly.

LEAD CANYON.—John T. Erwin, W. Fuller (alias Tamarack) and W. Bray came over the Inyos from Saline Valley last Wednesday. They found twenty inches of snow on the summit. The party opened a prospect on the east side of the Inyos, nearly due east from Independence, about three months ago. A body of ore was soon found that looked very promising, but how to get it to the railroad was an all important matter. A teamster was asked to examine the route, and after doing so said he would haul the ore to Big Pine Station for \$200 a ton. The ore is worth about \$150 a ton, and the miners were not willing to pay a bonus to the teamster of \$50 a ton, just for the fun of getting out the ore. They examined the mountain above their mine, found a feasible route for a road, worked on it two months, and now have a good way out to Independence Station a distance less than twenty-two miles. A contract has been let to Charley Mates to pack the ore for twenty dollars per ton. Charley will begin packing in a few days. The miners are confident that with a little more work on their road the cost of packing can be reduced to fifteen dollars per ton. These parties report having four first-rate prospects, yielding ore right from the surface. They say that right in their neighborhood is the most promising country for prospectors any of them has ever seen.

DEFIANCE.—As work progresses in the Defiance mine the recent strike develops into greater importance. The ledge is reported to be fully five feet wide, of solid ore. The most convincing proof of the extent of the ore body, and the facility with which ore can be got is found in the fact that Mr. Reddy has arranged with J. S. Gorman to start up the furnace and make a run on the ore between now and the holidays.

MARBLE SHIPMENT.—The first shipment of marble from Owens Lake has been made. The blocks shipped were as large as could be banded, or carried on the cars. The marble is pure white, and of very fine grain. Mr. Luce has explored the ledge farther up the mountain, and finds that it is very extensive. Another shipment of marble was made from Swansea last Thursday. Part will be delivered at Sacramento and part at San Francisco. Mr. Luce went along to dispose of the marble. Soon after January 1st the Swansea furnace will be started up on ore from Cerro Gordo. Teams are now hauling ore to the furnace, and already there is a good deal on the ground. A large quantity of slag at the furnace will be worked over; assays show that this slag will pay well for working.

Mariposa.

A GOOD PROSPECT.—Gazette, Nov. 28: The old pioneer, David Hays, is engaged in sluicing the dirt and vein matter of a large dump at the Mexican mine, belonging to Captain Diltz, and that said dump which was created by the Mexicans is yielding some most beautiful quartz specimens besides coarse and fine gold in quantities sufficient, which proves conclusively that all that has been said about the Mexican mine is not fabulous. It has borne the reputation of being a very rich mine and will no doubt whenever opened, show as good rock as any quartz vein in that neighborhood. Dave worked at the sluice all night one night this week in order to take advantage of the falling rain.

Mono.

THE GORILLA MINE.—Bodie Free Press, Nov. 26: Mr. Winterhalter, of the Gorilla mine at Lundy, arrived in town last Friday and left Saturday morning for San Francisco. He has let a contract to sink an incline 50 feet, nearly at the face of their main tunnel, which is in about 785 feet, then run an extension of 75 feet besides advancing the main tunnel, about 75 feet. The Gorilla has done better this year than at any time previous, and the stopes look well, the ledge being nearly three feet wide, the ore averaging \$200 milling process. Mr. Winterhalter will return early in the spring.

Nevada.

TO DRIFT.—North San Juan Times, Nov. 28: The English Company at Badger Hill near Cherokee, this county, will hereafter work their mine by the drifting process. No more hydraulic lifting for them. For several months past they have been engaged in making a bedrock cut from the mouth of their tunnel to the breast of their diggings. The bedrock cut is about seven feet in width and 200 feet long. Their pay gravel is about 300 feet in length and from 12 to 15 feet in height. It is blue gravel. The bank above the gravel is from 75 to 150 feet in depth. It was the intention of the company to commence their drifting Thursday of this week, but

whether they did so or not we are not informed. They will enter the mountain by a drift eight feet in width and the same in height. They will start straight for the dividing line that separates their mine from the mine of the Milton Company about 350 feet distant from the starting point. From thence they will work their mine in all directions, and will prospect the ground of the Milton Company adjoining the English Company's ground. Mr. John Quick, the very able foreman of the English mine is of the opinion that the mine will pay \$20 per day to each man, worked by the drift process, from the start, and if our wishes will be of any avail it will pay more than that.

A POCKET WORTH HAVING.—Nevada Transcript, Nov. 26: D. R. McKillican & Co., owners of the Gold Run quartz mine (formerly known as the Copper Hill ledge) on the Middle Yuba river just opposite Orleans Flat, have been working the claim for six or eight months past at a small profit, the ore deposit growing better in regularity of formation and quality as the development of it progressed. A few days ago they opened a "pocket" that has yielded them according to our informant about \$10,000 worth of bullion, and this together with the improvements in the regular ledge matter causes the stockholders to feel the utmost satisfaction over their investment.

Shasta.

PAY ORE.—Shasta Democrat, Nov. 28: Clark & Co., at Quartz Hill, struck fine pay ore in a vein they cross-cutted in a drift from the main shaft. The ore in Tom Greene's new mine at Deadwood assays from \$60 to \$150 a ton. The sulphurets are very rich. Hon. Reuben Clark intends to make some improvements on his quartz mill at Quartz Hill. Vet Hull, Jones and Dufur recently struck a rich prospect a short distance west of Shasta that promises to be good. When the ore is roasted it yields lots of the "yaller" truck. Lowery, the boss pocket hunter, a few days ago struck something new near Centerville. It is an ore that is very heavy, and besides being very rich in corroded free gold, carries a metallic substance that greatly resembles black sulphurets of silver. It is the first ore of the kind found in the county. At any rate the ore is very rich in fine gold. The Winthrop Co., at Copper City has shut down the mill temporarily on account of the inclement weather preventing the extraction of ore. The company is running a tunnel which, when completed, will allow the extraction of ore in all kinds of weather. Since smelting was commenced the company has shipped nearly \$10,000 in bullion and not more than five tons of ore have been reduced per day. We are told that it is the intention of the company to enlarge its works next summer. Ollie Whitton came down from his Squaw creek mine last Sunday and reported striking a wonderfully rich gold quartz vein about four miles from the Lillian Maude. He says the vein is three feet wide and prospects in free gold \$1000 to the ton. Besides this three other new strikes were made recently in that camp that are said to be as good as any that have heretofore been struck on Squaw creek. If the many prospects are half as good as reported, Squaw creek is destined to be a famous mining district.

Siskiyou.

PICK AND PAN.—Yreka Union, Nov. 26: The Campbell hydraulic mine at Mugginsville is running full time with a large force. At Hamburg Bar all the river miners have pulled out except Martin Andrews who is still working and realizing big pay. J. W. Pierpoint writes that the Black Bear mine is showing up well and that the mill is running by water power, 16 stamps in motion. Mr. Daggett has a large quantity of ore ready for crushing and a force of men are engaged underground taking out more. Schroeder and Werner on the East Fork of Deadwood have struck richer quartz than ever and have made several new locations which are also said to be extremely rich. The San Francisco parties who were here a few days ago for the purpose of bonding the claim, failed, the terms not being satisfactory to the owners. An offer was made to sell the claim for \$100,000 if taken before the 1st of January next, which offer will no doubt be accepted as the price is more than reasonable.

Trinity.

MACHINERY FOR NEW RIVER.—Journal, Nov. 28: Mr. G. V. Healy recently arrived at Eureka with a one-stamp mill, a concentrator and steam engine, en route for New River where it will be put in operation on rock from his Modoc mine. The New River district is not "played out" by any means. It will yet prove a prosperous district.

Tuolumne.

DITCHES.—Tuolumne Independent, Nov. 28: The current of business life is now running through the veins of the county, and better times may henceforth be expected. At noon, on Thursday, the water which was turned into the ditches of the water company reached the places where it will do the most good, and there is now an abundance for mining, milling and all other purposes. The company has been at large expense in repairs and improvements, and the people will soon begin to reap the benefits of this necessary element to prosperity. The long season of inactivity in mining has been depressing to every business man. The late rain of last season falling on a light snow harvest in the mountains caused a rapid disappearance of the reserves of ice and snow which supply the miners in the summer and fall seasons. The consequence was that the water in the ditches failed at an unusual early date, and the continued clear skies of the first fall months caused depression throughout the county and gave rise to gloomy forebodings. The mining interest being prominent in this section, and thus paralyzed for want of the necessary element to give it vitality, every one was in the dumps and business suffered. Now all this will be speedily changed, it is hoped, and soon good times may come again.

WORK ON THE MOTHER LODE.—Union Democrat, Nov. 28: There is promise of great activity in mining operations along the mother lode at Whiskey Hill and Quartz Mountain during the coming year. The outlook for that section has not been so hopeful for some years, and the prospects are based upon actual development. From a gentleman well acquainted with the locality we learn that there is a number of mine-owners have fine showings in their properties and are preparing for a busy season. John Collins, who is working the property under a lease, is breasting out ore from a four-foot vein in the Alabama and will shortly start the mill up on it. Good judges estimate that the rock being extracted

will mill from \$10 to \$15 per ton. W. N. Harris is running the Little Gem 10-stamp mill on ore from the Juaniata. Three men working in a six foot breast take out sufficient ore to keep the mill running 12 hours out of the 24. Mr. Harris says his rock will pay from \$10 to \$15 per ton. The Crystalline mill has started up for a long run. A breast about 20 feet wide is being taken down. All of the rock, which averages about \$8 per ton, is run through the mill. All the stamps of the Hespeler mine are going in good average rock, and Capt. Bowman reports the mine in splendid shape. The App mine is also looking well, and the mill will considerably swell the bullion shipments.

NEVADA.

Washoe District.

HALE & NORCROSS.—Enterprise, Nov. 28: The main south lateral drift on the 3100 level is being pushed steadily ahead, skirting along the eastern side of the ore vein, running in very favorable vein matter, quartz, porphyry, and clay. The drift is west of north, following the main trend of the ore body and keeping in good working ground, where any trouble from water is avoided. When the proper point is reached, one, two or three crosscuts will be made westward into the ore vein. Good prospects are found on the 3100 level, but the principal work of the mine is confined to the 3100 level.

CHOLLAR.—On the 3100 level the main lateral drift south was in 500 feet last evening, still following along the west side of the heavy quartz ore vein and keeping in the black dyke formation bordering the west country rock or diorite of Mount Davidson. The formation has become a little harder since last report, but is of the same general character, the air is good and excellent progress continues to be made.

SIERRA NEVADA.—Work in the face of the main north lateral drift on the 520 level has been resumed since last report. It has attained a length of 100 feet north from the shaft, and it has been advanced 84 feet further, making a total of 1085 feet. The face is in clay and quartz, with a little water coming in. All other drifts or crosscuts on this level are suspended at present, and work concentrated in the advancement of this main lateral drift northward.

CON. CALIFORNIA & VIRGINIA.—About 125 tons per day continues to be the average daily yield from the 1750 level, worked on company account, reduced at the Morgan mill, battery samples assaying \$22. The northwest drift on the 1650 level is in 318 feet, going after the old California ore stopes and leavings. The ore yield from the Jones lease section, between the 1200 and 1400 levels, has been increased to 120 tons per day, which is reduced at the Eureka mill.

CROWN POINT.—Quite an increase of excellent ore has been coming during the last week or so from the new stopes of the 1700 and 1750 levels which added to the large amount of lower grade ore from above the 1400, keeps all the mills running on it well supplied. The Belcher 1700 level is also turning out some tolerably high-grade ore. The two mines give a daily yield of nearly 500 tons.

YELLOW JACKET.—One hundred and seventy-five tons per day continues to be the regular yield from the old upper workings down as far as the 1350 level. The main lateral drift on the 1700 level from the Crown Point through the Kentuck has not yet reached the ore body expected to be developed by it in the northern section of the mine at that depth.

OPHIR.—On the 400 level the south lateral drift is now in 235 feet from the main west crosscut from the Mexican shaft. This drift is all the way in low-grade ore, showing better as it advances to the south. A crosscut west, started from it 180 feet south from the main west crosscut, has been advanced 47 feet, showing, however, no improvement of material thus far.

ALTA.—Some quartz of very fair quality is being found in the explorations of the 700 level, near the connection recently made with the upraise from the 950 level, and a good air circulation being established, working facilities are much improved, and a good ore body may be encountered at any time.

MEXICAN.—The two lateral drifts north and south recently started 200 feet east from the main lateral drift, in a strongly mineralized point of the ore vein, are in respectively 90 and 98 feet, and making good progress.

GOULD & CURRY.—West crosscut No. 2, 170 feet south of the north line, or opposite the shaft, has been extended 52 feet, making a total of 152 feet. The matter continues the same as at last report—hard, dry vein matter.

UNION CONSOLIDATED.—The crosscut east on the 500 level, 100 feet south of the Sierra Nevada line, is in 277 feet from the main lateral drift, having been extended 32 feet. Material, very promising vein matter.

BEST & BELCHER.—West crosscut No. 3 on the 1000 level has been extended 46 feet, making a total of 183 feet. Material, vein porphyry, clay and a little quartz, with a slight seepage of water.

KENTUCK.—Sufficient ore is being extracted from the mine in the old workings, above the 1300 level, to keep the Rock Point and Douglass mills steadily running.

Columbus District.

HOLMES.—True Fissure, Nov. 29: The ledge is very strong and produces well. During the present week we will commence work above the 5th. I think this ore body will extend up to the surface in front of the ore bodies that were worked by the Northern Bell Co. This section will produce a large amount of fine milling ore. We have not worked this ground above the old 6th level. The drift that we now call the Creer drift has been called the 2d level west. We have developed a fine body of ore in this drift. This ore is on the same ledge that the hot spote is on. The ore looks the same and the yellow chlorides are very rich. The 5th level crosscut has attained a total height of 94 feet, with no change in its general appearance. Everything at the mill and mine is in good order and working well.

MOUNT DIABLO.—We will finish cutting out the chute for the 7th level in a few days. The west drift on the 6th level is in 476 feet, and there is a small streak of low-grade ore showing. The east drift on this level is in 215 feet, and the face shows favorable ground for ore.

COLUMBUS CON.—Work was resumed in this

mine some time since, but up to date no material development has been made. Two prospecting drifts are being run, one east and the other west, but so far nothing of any consequence has been encountered. A raise has been started from the 200 level which presents a favorable appearance. Since the resumption of work no ore has been extracted.

CLIMAX.—The tunnel has been driven 185 feet in extremely hard ground. It will tap the ledge at a depth of 200 feet and will open up the mine in good shape, so that the boys will be able to take out considerable ore.

VICTOR.—Martin & Baker, as a result of twenty days' work, shipped eight tons of ore to Selby & Co. They received the returns the other day and find themselves \$300 clear ahead.

GENERAL GRANT.—William Dunlap and partner will start operations in a few days.

SILVER STAR.—J. L. Callison is doing his assessment work.

Eureka District.

ANOTHER \$1,000 DIVIDEND.—Eureka *Sentinel*, Nov. 28: The Silver Connor mine on Prospect Mountain continues to yield well, and during the past month there were shipped from the property to the Richmond reduction works 107 tons of ore, which netted a sufficient amount to allow its four owners to divide among themselves yesterday about \$1,000. These dividends have been monthly now for some time past, and judging from the limited amount of work done in the mine it is probable they will continue for years to come. The property is so located on Prospect Mountain that it is difficult to park ore down from it in the winter, when roads are bad, and heretofore the mine has been closed down during the season. It is probable work will be continued this year until Christmas, when each of the owners will doubtless again pocket out of the net profits \$250 each.

ORE SHIPMENTS.—During the week ending yesterday ore shipments were made from the mines of the district to the two reduction works in town, as follows: To the Richmond works—Water Jacket mine, 4 tons; Matamoros, 2; Continental, 2½; Frazier & Molino, 29; Excelsior, 53; Republic, 14; Fairplay, 17; Silver Connor, 107; Lone Pine, 22; Broy, 12; and Fourth of July 7. To the Eureka Con. works—Dunderberg mine, 54 tons; Gila, 1; Queen Elizabeth, 1; Florence Osgood, ½; Bloomington, 1; Perseco, ¼; Taylor, 1; Estor, 1, and Alexandria 9.

THE JACKSON MINE.—Excellent progress is being made in freeing the 600-foot level of the Jackson mine of the 12 feet of water that accumulated there during the past three years. The work was commenced on Wednesday last, and yesterday afternoon we were informed by Superintendent Shaw that it had been lowered six feet, and that by Tuesday next he expects to have the level entirely freed so that the miners can enter it and prepare for prospecting work.

Ophir Canyon District.

HIGH GRADE.—Belmont *Courier*, Nov. 24: Work goes bravely on in the Twin River Company's mine in Ophir Canyon under the able management of L. J. Hanchett. It is expected that the mill will soon make a run on ore from the mine. The ore which is extracted is generally of a high grade and therefore the run may be expected to prove a profitable one.

Peavine District.

MILL AND FURNACE.—Virginia *Chronicle*, Nov. 28: A mill has been built at Peavine, near Reno, with a furnace and both attached for working refractory ores, by Messrs. Halleck and Griffin. By their process it is claimed that the \$10 refractory ore now on the dumps at the mine in that district can be reduced to bullion, and leave a margin for the owner. The ore is crushed, roasted and subjected to a chemical bath, the secret of which has not been made public.

Rebel Creek District.

OHIO ORE.—Silver *State*, Nov. 26: E. O. Conner's team arrived here yesterday with 12,000 pounds of ore from the Ohio mine at Rebel Creek. The roads are so bad that the team did not bring much over half its usual load.

ALASKA.

PANNING OUT.—Alaskan, Nov. 7: From reliable sources we learn that quite a number of miners will winter on the White and Stewart rivers, where they are panning out from \$25 to \$30 each per day. Thomas Boswell, Jeremiah Berthold, Frank Moffat, Richard Paplin, Peter Weiberg and Francis Fraser are located about 60 miles above the mouth of the Stewart, and are making the amount stated above with rockers. Hugh and Albert Day, Isaac Powers and Stephen Custer are at work on a bar 16 miles up the Stewart. J. P. Chapman, Chas. Powell, Hen. Matteson and Franklin will winter on the White some distance above the mouth, where they will trap and hunt until the weather is again favorable for prospecting and mining. Joseph Ladau, Michael Hess and Thomas Williams are at the mouth of the White, where they will also hunt and trap during the winter. The White river takes its name from the color, or rather lack of color, of its water. The New Racket, a small steamer plying on the Yukon, was up the Stewart river the latter part of August, and landed \$1500 worth of provisions for the party of six first mentioned above. Another steamer called the Yukon came up as far as Fort Reliance. It is sincerely to be hoped that these hardy miners who have penetrated so far into an unexplored wilderness may find gold enough to enrich themselves to almost any extent within the limit of a reasonable wish. They well deserve all they can find, even though the same total mounts way up into the millions.

COLORADO.

JOE REYNOLDS.—Georgetown *Courier*, Nov. 24: A shipment of one carload of ore was made from the property this week. The mineral came from the Kavanagh & Daily lease on the tunnel level No. 2, lode.

COLORADO CENTRAL.—According to the annual report, the Colorado Central has netted its stockholders about \$120,000.

PAY ROCK.—The Pay Rock tunnel level, Silver Bank, and 90-foot levels are being pushed ahead very vigorously, and although this causes a great deal of dead work, the policy is one of true mining, namely, to keep plenty of ground opened up ahead.

During the past week large shipments of ore have been made from this mine, both by company and lessees.

SNOWDRIFT.—During the last year's operations of this property considerable work has been done. The work done has been principally in development, although one party of lessees took out in seven months \$2800 worth of ore, over hauling and milling charges. The average net value of all the ore mined was \$160 per ton, and mill-runs were had of 649, 679, 779 and 864 ounces silver per ton. On the Daniel Peters lode some stoping was done, and ore as high as 454 ozs. mined in the upper level. The lower level was cleaned out and 250 feet of double track laid. The property is in good shape, and ought to yield largely the coming year.

IDAHO.

LAVA DISTRICT.—Wood River *Times*, Nov. 28: All the mining prospects that are being worked are showing exceedingly well, and many of the prospectors have outfitted themselves for the winter, and settled down to work on their claims. Several bonds have been taken on different properties on Lava creek, which will be worked all winter, besides two or three others which will be worked under leases.

THE DONOVAN GROUP.—The boiler for the Donovan group of mines (which is incorporated under the name of the Idaho Gold Mining Company of Utah) was hauled through town to-day, on a truck belonging to the Hailey Transfer Company. At the Donovan mines and mill-site, 26 men are kept busy mining or erecting the mill. The timbers are all framed, the machinery (excepting the boiler) is already on the ground; a man is on the way from Boston to see that the Wiswell electric machinery is properly placed, set and started, and to make the first trial run and cleanup.

PLACER MINING.—Cor. Helena *Independent*: The California Ditch Company, composed of W. J. Hawkins, now of Murray, James Steel, of Portland, Ore., and two others, have completed a water flume of 1000 inches capacity from near the head of Pritchard creek (taking in the waters of Bear and Butte gulches) running along the north side of Pritchard creek and on around on the hill side to the north, to the head of Daisy gulch, which is a south tributary to the east fork of Eagle creek. This flume is for the purpose of supplying water for hydraulic sluicing on the hill diggings north of Pritchard creek, and the placer grounds in Dream, Missoula, Dry Alder and a number of other gulches which come into Pritchard creek from the north. The Coulter Flume Co. are at work building a flume four feet wide and one and a half feet deep, still higher up the mountain side than the California Ditch Co.'s flume, which will be eleven miles long when completed. The Dry Gulch Co., under the management of W. J. Hawkins, who owns a large interest, are working their placer grounds a quarter of a mile northwest of Murray, in Dry gulch. They keep two hydraulic pipes running night and day. Bedrock is from three to fifteen feet deep. The gold is fine, coarse, and nugget gold. W. J. Hawkins showed me a part of a tin cupful of the gold—over \$200 worth—the cleanup of a twenty-four hours' run; also, a \$36 nugget, which one of his men had picked up out of the gravel in the claim that day. A Louisville, Ky., Co. is working the Golden Chest lead, two miles northeast of Murray in Reeder gulch. They pay out \$6000 monthly for wages and supplies. They have ten 140-pound stamps dropping ninety times a minute, day and night on the \$130 per ton free milling gold quartz, taken from an eight foot ledge just back of the mill upon the mountain side. The ledge is tunnelled to the depth of 350 feet, and it still holds its width and richness. About two miles down Pritchard creek the Golden King Mining Co., composed also of Louisville capitalists, own a number of leads known as the Skookum Group, two of which are being opened up under the immediate supervision of Richard A. Pomeroy, late of Colorado. This company have completed 250 feet of flume from the bed of Pritchard creek, up along the hillside, to a point above a site on which they are preparing to erect a 40-stamp mill. They now have men at work on a large boarding house for the men they will employ. The company, Colonel Pomeroy said, did not wish as yet to mention the extent and quality of the veins in their numerous mines. In the Beaver creek country, the Potiso Ditch Co., composed of Denver, Colorado, men, have two ditches, one higher up on the mountain side than the other, taking the water out of the upper end of Beaver creek, running down (west) along the north side of the creek to Potiso gulch, another tributary of Beaver creek. Two placer claims are being worked in Potiso gulch. In American gulch, a small side gulch putting into Potiso, Coy & Parks have been taking out twenty to thirty dollars a day to the man for the last six months. On Trail creek, another north tributary putting into Beaver creek at the town of Delta, the Myrtle Mining Co. are working placer ground which is twelve feet to bedrock. Half a mile above the town of Myrtle, on Trail creek, another large piece of placer ground is being worked by Bosse & Co. On these two claims the surface gravel is removed by mule teams and scrapers, the dirt next to the bedrock is then washed in sluice boxes. Three other placer claims, which are said to be paying well, are being worked in Placer gulch, which puts into Trail creek from the east, just above the town of Myrtle.

WILLIAMS' FORK.—The veteran prospector, Mr. E. S. Streeter, returned from Williams' Fork last week, bringing with him some excellent specimens of silver "sulphurets," showing the quality of surface ore in that locality. These specimens assay as high as 3000 ozs. silver to the ton. Mr. S., together with others, has been prospecting in that district for the past three years, and has met with good results. During this time he has been operating principally on Candler mountain, where he has located a number of valuable claims. The district shows well for surface work. No deep operations have yet been made, the deepest workings so far not exceeding 150 feet; but indications at this depth and at surface show flatteringly for a good mining camp in the future. What is wanted now is capital to develop the resources of the section. Among the prominent mining operators of the Forks may be mentioned Wilson & Co., W. Cozens & Co., Webb & Sanders, Mitchell Bros., and Katt & Co., who are working properties with good showing. They have large dumps, which they think will run from 20 to 40 ozs. in silver to the ton, and there will be an

effort made to build a furnace for the purpose of utilizing these low grade ores. It is supposed and earnestly hoped that the B. & M. railroad will be built down the Grand, and give an outlet and boom to the mines of Williams' Fork. In 1880 the country was widely prospected, and hundreds of claims were located upon which no work has since been done. Their abandonment leaves them free to be relocated by any prospector that wishes to. Very few patents have been obtained on properties in the district. The country will one day undoubtedly be a great mining camp.

CONCENTRATOR.—Idaho Springs *Gazette*, Nov. 28: The concentrator is running steadily on concentrating ore. A large quantity of nice smelting ore is purchased by Gleim & Co., Charley Roberts, a denizen of Cascade district, is doing much towards opening up the resources of that camp. He has control of some valuable property in that district, and has lately started up an enterprise which, with but a small outlay of money and muscle, is certain of success. Commodore Beazy has done a great deal toward opening up our mineral resources. Some years ago he started a tunnel up Virginia canyon, on what was supposed to be the extension of the France. The tunnel was driven a long distance and no pay was struck. A few days ago Vic Beazy, in doing the Chaffee work on the surface just over the tunnel, uncovered a small streak of ore. A sack-full sampled nearly \$2000 a ton. The tunnel is not upon the right vein. How many mistakes are made just like this, then the property condemned? The Union Smelting and Refining Works, which used the Campbell patents for roasting, will not be started up again. Not for any reason of the smelting or roasting process, but because the works were not erected to handle the ore economically as far as labor was concerned. The works were originally the old Star, and then the Wilson smelter, and were fixed over and over. It took too many men to handle the product.

LEADVILLE.—Tribune *Republican*, Nov. 28: The Tenderfoot mine at Leadville is now demonstrating what nerve will accomplish when rightly applied to mining. Good mining work, however, is being done in all parts of the carbonate camp in both old and new properties, and the prodigal waste and lack of judgment so characteristic in the past are no longer striking features. Properties on Fryer Hill that were left as abandoned prospects several years ago are becoming productive under the thorough workings of the present time. Played out mines are also producing, and of this class the Chrysolite continues shipping considerable high-grade ore from the body opened up four weeks ago. The ore is holding out nicely to the south and east, and the possibilities of the body still remain undetermined. It is reported that the lessees working in the northern portion of the Little Chief mine have disclosed the extension of this ore body 65 feet distant from the nearest workings in the Chrysolite. The production of ore from other portions of the Chrysolite mine is about up to the average of the past few months. The Chrysolite mill is running regularly on low-grade free-milling ore, not adapted to the smelting process.

MONTANA.

MOULTON.—Butte *Miner*, Nov. 28: The stopes show the average quantity of good ore, and all the machinery is in first-class running order.

SILVER SAFE.—Considerable second grade ore is being taken from the mine and sent to the mill. No first-class rock is being taken out at the present time.

ALICE.—The bullion output has been fully as large as usual. All the machinery is in full blast.

ELM ORLU.—In the north cross-cut to the ore body the drift is in vein matter all the way, showing some streaks of splendor ore, but the main body has not yet been reached.

BLACK ROCK.—All of the ore stowed away on the 65-foot level has been hoisted out of the way, and most of it has been delivered at the Colusa smelter. The ore streak fills the shaft, and assays 57 ounces per ton, and there is no waste to hoist. The company has made a contract with the Colorado smelter to ship to the latter 10,000 tons, more or less, of its ore, of a grade from 20 ounces per ton upwards. It will, on account of the manganese it contains, be used as a flux.

NORTH STAR.—The drifts east and west in the 160-foot level show very large bodies of ore, and some handsome assays are returned. No ore is being taken out for the present, although there is plenty of it in sight in both east and west drifts on both levels, and all work is being concentrated in the drift for the Salisbury lode.

GENERAL NOTES.—The Wild Bill continues to look as well as ever, French & Co. are pushing work rapidly on their lease of the Ophir. There will soon be a new shaft house built over the North Star shaft. The Butte smelter between the depot and the Colorado has shut down again. The Amy Silversmith shows very well, and the vein is said to be large and regular. Clark's Fraction keeps the teams going, and is sending some splendid ore to the mill. The Little Darling has some very rich quartz, and the vein shows exceedingly well. The Poser folks are pushing work as fast as they can, and are taking some very good ore from the bottom of the incline. The lessees of the Minnie Irvine are happy as they progress with their work, and it is said that the ledge is improving all the time. Yesterday the Lexington hung up thirty stamps, some repairs having become necessary. In a day or two they will be hammering away again. The Neptune still sends a quota of good ore to the mill, and from present indications can continue to do so as long as the management wants to. At the three Unions the work of opening up continues, and it is reported to be the intention of the management to keep the vertical shafts going down as rapidly as possible. The Clear Grit has a good sized pile of ore on the dump, upon which the teams now hauling make a small impression. Their ore dump is small, and just enough ore is being extracted to keep it filled up.

NEW MEXICO.

WATER CANYON.—Socorro *Bullion*, Nov. 28: McLeish & Leddy have done some excellent work, with good results, on the Maggie Merchant. Wm. Mahan owns a very promising claim near the Jane Bowman. He is now sinking a shaft upon it. The L. V. & St. L. Mining and Smelting Company are placing more capital in the Spotted Prince. It looks well.

MAGDALENA DISTRICT.—Jose Robles is working the Aztec and Montezuma. Charles Carleson and Frank Staup are delving in their valuable claim. Dr. Abernethy is working the Little Luella and Hermosilla for Colonel Eaton. Hollenbeck & Hasty have inaugurated work in their promising properties. Percival Henderson is now superintending operations in the Juanita mine.

PUEBLO DISTRICT.—Shep. Lewis is dumping pay dirt out of his claim. Shipment of Gutierrez ore to the B. M. & M. Co.'s mill continues. Huston & Holmes are working the Copper Button, McKay and Plain View. Night and day shifts are working constantly in the Pajaro and Parnerio mines. W. H. McGehee and W. H. Patterson are developing their Meramac mine successfully. The Metzger mine, owned by Brittenstene & O'Rear, is dumping pay mineral daily. Developments of the Golden Queen commenced this week, and it is furnishing a good-grade milling ore. Shipments of rich silver ore are now reaching the Billing works from the Sophia, which is exploited by R. N. Sniffen.

LEACHING.—The Sierra Grande lixiviation works, are expected to be in operation sometime in the month of January. Mr. Russell has made an engagement to spend six weeks at Lake Valley for the purpose of putting the plant in good working order. No mining work will be done before the 1st of January. There are 6000 tons of ore ready for the mill now. It is probable that some custom work will be done. Frank Bell, who, with Mr. Skillicorn, is working the Pacific No. 2 mine, at Pinos Altos, was in town a few days ago, and had with him some remarkably fine specimens of gold rock. Several pieces showed the cleavage planes to be filled with a perfect mat of wire gold. Owing to the late hour last week which the *Enterprise* received definite and reliable information concerning the transfer of the McGregor mines, at Georgetown, the account of that important sale was necessarily brief, although the chief facts were given. The purchasers took possession on Wednesday of last week, and on Friday following, the deeds of transfer were recorded. The McGregor and the Grampian are the mines which have been worked principally and out of which the larger part of the ore produced has come. The books of the company show a product since 1873 of \$280,000, and in addition to that sum it is estimated upon a reliable basis that upwards of \$25,000 worth of ore has been extracted which is not accounted for on the books.

OREGON.

THE VIRTUE MINE.—Bedrock *Democrat*, Nov. 24: Mr. Terry, the new superintendent under whose directions work will be resumed at the Virtue mine, east of this city, returned Sunday from San Francisco. Yesterday he left for the mine, taking with him supplies for the few men who are already at work there. As yet we are unable to state how many men will be engaged this winter, but we understand there will not be a very large force engaged, as the work is of such a character that a large number of men cannot work to any advantage. The first work will be the cleaning out of the old tunnel and main shaft and putting in timbers where the old ones are considered unsafe. Parties having contracts to deliver wood and lumber have fulfilled the terms thereof and everything is in readiness to commence operations. The output of the Virtue a few years ago, when properly managed was enormous, and there is no doubt but what it will pay as well in the future. With the Virtue, Mammoth and several other well known mines in the vicinity in full blast in the spring, and Pine creek booming, Baker City's interests will receive an impetus that will crown her the Queen City of Eastern Oregon.

PINE CREEK.—A friend writes us from Pine creek as follows: Joseph Luce, general superintendent of the O. G. M. Co. has forty-two men engaged in building bridges on the road to the mine, cutting timber for tunneling the tunnels and shafts, etc. He expects to be in full running order, boasting by the first of December. The company have also put up an office in town and one at the mine, and are building a boarding house 16x50 and a shaft-house 16x40. Many persons acquainted with Mr. Luce have informed us that he is pushing matters expeditiously and making a good showing on the Whitman, where these works are being erected. By spring he will have everything in shape to ascertain the value of the ledge and everything requisite for the successful working of the ore. Other discoveries are being developed with commendable energy, all interested having the utmost confidence in the permanency and wealth of the camp. There is considerable snow in that district which ends the prospecting season for this year, but men who spent the summer the camp/claim that there will be as many and as in rich discoveries made next season as were made in the one just ended.

UTAH.

REVIEW.—Salt Lake *Tribune*, Nov. 28: The week has been prolific of storms, alternating with sunshine. The movement of the metals has been brisk, though no great event has marked the seven days. It has been a good week for dividends, however, the Ontario giving notice of its eleventh dividend of 50 cents a share, aggregating \$75,000, and making the total dividends of the year \$900,000, or \$6 per share; it will be paid on the 30th. The Honerine paid its fifth dividend on the 25th in Boston, five cents a share, aggregating \$12,500; total of five dividends, \$62,500. The shipments out from this city for the week ending Saturday, November 21st, inclusive were 1,279,256 pounds. The receipts of bullion and ore in this city for the week ending Nov. 25th, inclusive, were—of bullion, \$127,734.99; of ore, \$26,049.18; a total of \$153,784.17. The week before the receipts were \$109,267.57, of which \$86,657.57 was bullion and \$22,610 was ore. The output of the Ontario for the week was \$35,482 of bullion, raising its total for the year to \$1,476,945.21, from which \$900,000 in dividends has been paid, as noted above. The property is in first-class shape in every respect. The Stormont sent up two bars of silver on the 20th, \$2800. The product of the Hanauer smelter for the week was nine cars of bullion, \$27,520; of the Germania, six cars, \$12,859.34. The Alice sent down during the week 46 bars of bullion, \$48,273.65. Ore receipts were as follows: From the Honerine, \$13,231.18; Merwin, \$1406; Lead Mine, \$1200, Utah. From the Queen of the Hills, \$7965; Bannock, 8½ tons, \$2247, Idaho.

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

IRON CASTINGS OF ALL DESCRIPTIONS.

A. T. DEWEY, } Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED
W. B. EWER, } 1860.
GEO. H. STRONG, }

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enabled us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department to, San Francisco.

YOSEMITE G. & S. M. Co.—Nov. 28th. Location, Fresno Co. Capital stock, \$15,000,000, in 150,000 shares. The Directors are Robert Ray, M. San Pedro, E. Derbec, L. Dutertize and P. G. Somps.

CALIFORNIA SCHOOL OF MECHANICAL ART.—Nov. 1st. The school was founded by a bequest from James Lick, and is provided for the teaching of arts of life, workers in wood, iron and stone, and the institution is to be open to youths born in California. Directors, Horace Davis, John Earl, A. S. Hallidie, Lorenzo Sawyer and J. D. B. Stillman.

McCUE CARRIAGE FACTORY.—Nov. 1st. Object, carriage manufacture. Capital stock, \$25,000. Directors, Louis T. Haggin, William Willis, John Nolan, Julius C. Green and Irwin C. Stump.

SIERRA-PHENIX M. Co.—Nov. 1st. Capital stock, \$500,000. Directors, Arthur F. Price, J. F. Evans, H. J. Owen, J. R. Hall and A. B. Paul.

HOME MUTUAL LOAN AND BUILDING ASSOCIATION.—Nov. 1st. Object, to make loans for acquiring real estate. Capital stock, \$2,000,000, in 10,000 shares. Directors, Charles Macabe, Charles K. Clark, Geo. M. Mitchell, Edward N. Harmon, Edward C. Hughes, Henry G. Phillips, Monroe Greenwood, George Mearns and Wm. M. De Wolf.

ROUND VALLEY MINING CO., Nov. 1.—Location, Plumas Co.; capital stock, \$1,500,000, in 150,000 shares. Directors, A. D. McIntyre, J. L. Bransford, George W. Handy, John Lloyd, N. W. Griswold, Levi Jenks, Henry C. Hyde.

COSMOPOLIS MILL AND TRADING CO.—Nov. 1. Object, to trade in lumber in Washington Territory; capital stock, \$100,000. Directors—C. F. Leavenworth, J. M. Riley, M. G. Toenfen, J. J. Scrivner and John L. Boome.

SPANISH GRAVEL MINING CO.—Nov. 1. Capital stock, \$1,000,000. Directors—Charles E. Shattuck, Thomas H. Henderson, John W. Stewart, Fred E. Shearer and George E. McConnell.

EMERALD MINING CO.—Nov. 2. Capital stock, \$5,000,000. Directors—A. Perutez, James Salfsfohn, William Adelsdorfer, Bende Leon and S. Bergmann.

TYROLESE MINING CO.—Nov. 2. Capital stock, \$100,000 in 10,000 shares. Directors—A. Perutez, James Salfsfohn, Wm. Adelsdorfer, Bende Leon and S. Bergmann.

Mining Share Market.

Stocks seem to remain at about the same figures, there being little fluctuation apparent. Active development work is going ahead, as usual, in the mines of the middle section of the Comstock. The good ore veins and streaks heretofore developed in the Hale and Norcross assay finely. The main south lateral drift in Chollar, on the 3100 level, is now 500 feet long and rapidly nearing the north line of the Potosi mine. No crosscutting or sinking deeper is talked of at present. A full force of miners are employed in the Gold Hill section, including the Yellow Jacket, Kentucky, Crown Point and Belcher, and also in the old bonanza mines of the north end—the Consolidated California and Virginia. The Ophir bids fair to skin out some good ore resources before long. Over 1000 tons per day is the regular product of the Comstock at present, with a prospect of an increase. Meanwhile a large amount of prospecting work is being done with a judicious view to further ore development and supply. The Carson river is booming full of water, giving every mill along its course its full requisite of motive power, with a plentiful surplus flowing away toward the Sink. Every mill in the section is now running to its full capacity on ore of some kind.

Bullion Shipments.

Argus, November 26, \$11,831; Banner District, 26, \$4500; Lexington, 24, \$25,760; Moulton, 25, \$37,480; Dexter, 25, \$4944; Alice, 25, \$31,580; Silver Bow, 25, \$10,226; Barber's Mill, 29, \$5000; Calico Mill, 24, \$8400; Hanauer, 25, \$10,600; Ontario, 25, \$35,482; Meridian, 26, \$1406; Alice, 26, \$9496; Hanauer, 26, \$3300; Queen of the Hills, 26, \$1500; Germania, 23, \$5941; Hanauer, 28, \$9500; Crescent, 28, \$2700; Queen of the Hills, 26, \$2500; Hanauer, 29, \$3100; Germania, 29, \$1953. The hanks of Salt Lake City report the receipt for the week ending November 25th, inclusive, of \$127,734.99 in bullion and \$26,049.18 in ore, a total of \$153,784.17.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

MINING SHAREHOLDERS' DIRECTORY.

COMPILED EVERY THURSDAY FROM ADVERTISEMENTS IN MINING AND SCIENTIFIC PRESS AND OTHER S. F. JOURNALS.

Hot and Cold Baths Free. None but most obliging white labor employed. Free Coach to and from the Hotel.

MONTGOMERY BROS., Proprietors.

AN EXTRAORDINARY RAZOR

HAS BEEN INVENTED BY THE QUEEN'S OWN COMPANY, of England. The edge and body is so THIN and FLEXIBLE AS NEVER TO REQUIRE GRINDING and hardly ever setting. It glides over the face like a piece of velvet, making shaving quite a luxury. It is CREATING A GREAT EXCITEMENT in Europe among the experts, who pronounce it PERFECTION. Two dollars in buffalo handle, \$3 in ivory. Every razor to be genuine, must bear on the reverse side the name of NATHAN JOSEPH, 641 Clay street, San Francisco, the only place in the United States where they are obtained. Trade supplied; sent by mail 10c. extra, or C. O. D.

WANTED.

Situation by a Competent Chemist,

Graduate of the Imperial Polytechnic Institute at Graz, Austria. Expert analyst, assayer, technologist and metallurgist. Would also go to Spanish America. Address care of F. SUSTERSIC, Big Spring, Howard County, Texas.

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 500 South 10th St., Philadelphia. Branch Office—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

HEALD'S BUSINESS COLLEGE, 24 Post St. S. F.

Send for Circular.

INVENTORS, TAKE NOTICE!

L. PETERSON, MODEL MAKER,
258 Market St., N. E. cor. Front (up stairs), San Francisco. Experimental machinery and all kinds of models, Tin, Copper, and Brasswork.

Badges for All Societies,

Police, firemen, etc., presentation prizes or charms, in gold, silver, or metal, sold at society prices by the agents of the Universal Badge Manufacturing Co., NATHAN JOSEPH & CO., 641 Clay St., Workmen and K. of P. badges in gold, \$1 each, sent C. O. D. Trade supplied.

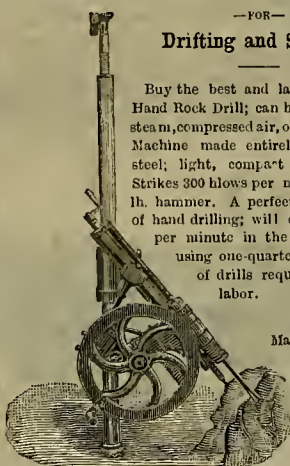

PATENTS. Thousands of inventors throughout the Pacific Coast can and will willingly attest to the promptness, reliability and success of Dewey & Co.'s U. S. and Foreign Patent Agency, No. 252 Market St. Elevator, 12 Front St., S. F.

CALIFORNIA HAND ROCK DRILL

—FOR—

Drifting and Sinking.

Buy the best and latest improved Hand Rock Drill; can be run by hand, steam, compressed air, or water power. Machine made entirely of crucible steel; light, compact and durable. Strikes 300 blows per minute with 7-lb. hammer. A perfect reproduction of hand drilling; will drill one inch per minute in the hardest rock, using one-quarter the number of drills required by hand labor.

Machines on exhibition at No. 32 First St., San Francisco.

Send for circulars.

C. O. BARLOW, General Manager.

THE CELEBRATED Woodbury Oils.

Pure, Perfect, Uniform!

The WOODBURY OILS are in use on the Central and Southern Pacific Railways, and on nearly every railroad and steamship line on the coast. We are not agents for other manufacturers, but have our own works, and adapt here all our Oils to the requirements of home machinery and our climate. We can show recommendations and records of tests, showing a saving to our customers of 50 per cent on their lubrication last year. Address

CHARLES J. WOODBURY,
123 California St., San Francisco.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

elevators, or electric lighting machines are in use; and generally in Cities and
Towns (where gas is obtainable) for all mechanical purposes requiring small
driving powers.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS!
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED.

PRICE, FIVE HUNDRED AND FIFTY DOLLARS
(\$550.00), F. O. B.

THE "TRIUMPH" TRIUMPHANT!

In a competitive trial recently had between two of the "Triumph" Ore Concentrators and the same number of "Frue" Vanning Machines, at the mill of the celebrated gold producing Original Empire Mill and Mining Company, in Grass Valley, Nevada County, Cal., the "Triumphs" produced thirteen and fifteen one-hundredths (13.15) per cent more concentrations than did the "Frue" Vanners, during a run of twenty-four consecutive days, or a net gold coin result of \$193.15, or \$3.30 per day, in favor of the two "Triumph" Concentrators.

These returns do not include the value of the amalgam saved by the "Triumphs" during the test; which will add to the net gain. The form of construction of the feed bowl is such that considerable amalgam is necessarily saved, which is lost on the "Frue" Vanners.

This trial was conducted under the personal supervision of the Manager and Superintendent of that Company, in a strictly fair and impartial manner, and with the sole view of determining, in the interest of that Company, the merits and demerits of the respective machines by a thoroughly practical test. A relation of the course of procedure, a concise analysis of assays, and a tabulated statement of the net bullion results, with accurate deductions therefrom, will soon be published in Circular form.

The superiority of the present construction of the "Triumph" over the form originally introduced, together with the demonstrated results of the above, and other trials had with the "Frue" Vanners, induce us to and we hereby accept the Challenge of \$1,000, flaunted by the Agents of the "Frue Vanning Machine Company," and hold ourselves in readiness to enter into a second competitive trial for that sum, at such place and upon such terms and conditions as may hereafter be mutually arranged.

We guarantee purchasers against all costs, expenses or charges incurred by reason of any infringements of any existing patents.

"Put up or shut up," and "Let the Best Machine win!"

JOSHUA HENDY MACHINE WORKS,

Nos. 39 to 51 Fremont St.,

San Francisco, Cal.

**THE
"TRIUMPH" ORE CONCENTRATOR.**

MINING MACHINERY, ENGINES, BOILERS, Etc.

We are manufacturing from Special Designs of the most experienced and successful Practical and Scientific Experts, Complete Plants for all descriptions of Mining Operations, as follows:

CONCENTRATING MACHINERY—Best and Cheapest, Cornish Rolle, all Steel Wearing Parts, Most Practical Styles of Two, Three and Four Compartment Double and Single Jigs, Sizing Screens, Patent Hydraulic Separators, Tables and Concentrators.

STAMP MILLS for Reduction of Gold and Silver Ores, whether free milling or base. Most useful and substantial styles of Single and Double Discharge Mortars, Wet or Dry Crushing.

STEEL SHOES AND DIES, Tappets and Cams, cheapest and best Blake Improved Rock Crushers and Automatic Ore Feeders, Superior Amalgamating Pans with wood or iron sides.

PANS FOR TREATING GOLD ONLY, Settlers, Clean-Up Pans, Retorts, Furnaces, Dump Cars, Hoisting Machinery, Cages, Landing Dogs, etc.

CORLISS, MEYER'S CUT-OFF AND BALL'S PATENT VALVE Engines of extra strength and durability.

STEEL BOILERS of Two Sheets only, Steel Economic Boilers, combining with the safety, durability and economy of the Stationary Boiler, the convenience and portability of the Portable. It occupies but little space, and is the best and cheapest boiler ever made.

WE ALSO MANUFACTURE SAW MILL MACHINERY.

We are also Sole Agents for the Gordon and Maxwell Steam Pumping Machinery, and carry a full stock of all kinds of Mill Supplies, including the

Albany Lubricating Compound and Oils.

1850. 1885.
RANKIN, BRAYTON & CO.,
BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves ALL THE AMALGAM GOLD AND SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

MINING AND SCIENTIFIC PRESS.

BY DEWEY & CO.,
Publishers.

SAN FRANCISCO, SATURDAY, DECEMBER 12, 1885.

VOLUME LI
Number 24.

A Kern County Mine.

A mine is being developed about five miles from Tehachapi station, Kern county, which bids fair to be one of the big mines of this State. The ledge is a peculiar one, lying very flat and the quartz being very soft. No blasting is needed, the ledge matter crumbling down easily under the pick. It was worked several years by its original owner in a desultory manner, he taking out some ore in the summer and crushing it with an arrastra. Last June it was purchased by some gentlemen of this city, who have since been working it.

An incline 120 feet long was first run in. The ledge at the mouth of this was seven feet wide, and at the inner end had widened to 13 feet. They then went 250 feet below and ran in a tunnel in the side of the mountain 350 feet, and when they struck the ledge it was 20 feet wide. They have drifted 100 feet from the tunnel on the vein and will drift 200 feet. If the ledge continues to look as well as it does at present a mill with a capacity of 100 tons a day will be put up.

While opening the mine considerable ore has, of course, been taken out, and 1200 tons have been milled, netting at the mill \$9.95 per ton. Some of the ore has run as high as \$15. But so large a ledge, and one so easily worked will pay handsomely with nine dollar rock. The ore is hauled a mile and a half to the Huntington mill, which the owners set up while prospecting the vein. A large percentage of the ore will go through the screens just as it comes from the vein, so soft and brittle is it. There are only occasional lumps of hard rock. The mine is owned by private parties and is being worked as a legitimate mining proposition. The latest reports from it are of a most encouraging character. It is called the Pine Tree.

Academy of Sciences.

Professor Davidson presided at the meeting of the California Academy of Sciences on Monday evening last.

Professor Edward S. Holden, the new President of the University, was nominated for membership, as was also Gen. L. H. Foote.

Horace Davis, William Norris, Leo Eloesser, W. A. Aldrich and J. Evans were declared to be the committee to nominate the regular ticket for officers for 1886.

Mr. Charles Burckhalter, of Oakland, presented a memorandum of observation of Nova Andromeda, on December 5th, from seven to eight hours, with his ten and a half inch speculum. At 6:45 P. M. he turned the telescope upon the great nebula in Andromeda, and tried various powers without finding the new star. After putting out all light in the observatory and resting his eyes in the darkness, he again observed the nebula at 7 hours, and almost immediately he saw the new star, but only to lose it again. He saw it half a dozen times but could not hold it over one or two seconds. The twelfth magnitude star preceding the nova was easily and distinctly visible all the time.

The weather was exceptionally fine and the seeing perfect. Mr. Burckhalter was joined by Mr. Stanford, who saw the star with much difficulty, although he saw the thirteenth magnitude stars situate between epsilon and epsilon² Lyrae easily with seven and a half inch stop on ten and a half inch speculum. The star is growing fainter rapidly, and Mr. Burck-

halter believes he has seen it for the last time, the favorable conditions at the time of observation being rare.

Baker's Quicksilver-Feeding Machine.

The accompanying engraving illustrates a little machine devised by C. H. Baker for feed-

QUICKSILVER FEEDER FOR QUARTZ MILLS.

ing quicksilver into the batteries of gold quartz mills. When this is done by hand, poor work is done from want of proper feeding of the mercury.

The machine will feed once in ten or fifteen minutes, or even once in thirty minutes, a large

A New Draft Regulator.

People who use open grates know very well that there is considerable waste of fuel in them, owing to the deficient means of regulating their draft. Even under the best of plans, a great amount of heat is drawn up the chimney with the product of combustion, the opening over

the grate having to be large to discharge the smoke.

A new device for regulating the draft in grates has been patented by W. Hunter, of this city. The plan is shown in the engraving. The cut shows the device as applied to fire-

IMPROVED DRAFT REGULATOR FOR GRATES.

or small quantity, as desired. The quantity is regulated in a moment by a screw without stopping. The machine is simple and ingenious. It is bolted to the upright post of a stamp-mill, and driven by a belt from the cam shaft, as shown by the illustration. One machine will answer for each battery of five stamps. It costs only \$35, with all the fittings necessary to put it at work. It weighs 70 pounds, and is sold by John Taylor & Co., of this city.

COAL from Eastern Arizona is sold in Los Angeles market.

It may be applied to brick-kilns, tubular boilers, etc. The regulator is readily put in fire-places already constructed. A test of the device can be seen at any time at the office of Hunter & Shackelford, 310 Pine St., in this city.

Trying a Debris Dam.

In the U. S. Circuit Court this week, when Judges Sawyer and Sahin were on the bench, the temporary injunction restraining the Liberty Hill Consolidated Mining and Water Company from working its hydraulic mines was modified, and it was allowed to carry on operations for fifteen days, between now and the first Monday in January, 1886, until which time the motions to dissolve the injunction or make it perpetual were continued. The complainant in this case, which is the second in importance among the slickens cases, is Peter Hardt. When Judge Sawyer enjoined hydraulic mining, he stated that if a successful method for impounding debris were discovered he would dissolve the injunction.

The Liberty Hill Company have constructed a dam which they aver will fill all requirements. The Court has therefore allowed the company to make the test for the brief time specified. The miners are perfectly satisfied as to the efficiency of these dams, but their opponents are not. If the miners are willing to risk their money on the result, they must have good reason for being sure they can impound the slickens. The result of this trial will be watched with interest.

Mechanics' Institute.

At the regular quarterly meeting of the Mechanics' Institute the Librarian's report showed a total membership of 2527, of whom 160 are life members. Library receipts for the two quarters, \$11,639.25; expenditures, \$9,242.63; books added, 1669. Total bound volumes in library, 39,293. Some 210 scientific books had been bought for \$783.52.

The Treasurer's report showed: Expended from Lick fund for scientific works, \$2,494.17; gross receipts from last fair, \$48,533.05; disbursements, \$27,349; net profits, \$21,174.05, which, added to \$1825.95 from other funds, permitted the payment of \$23,000 on the Pavilion mortgage, reducing it to \$110,000, on which \$550 monthly interest is now being paid.

President Cornwall, in commenting on the reports, states that the average annual rent receipts from the Pavilion, exclusive of the two months fair term, were about \$10,000. They were clearing, after paying mortgage interest, some \$450 monthly. The various branches of the Institute were in a very gratifying condition, and they relied on reducing the mortgage \$25,000 after the next fair. Attention was called to their indebtedness, incurred when the Pavilion was built in 1881, of \$240,000, since which the Institute had paid off the large amount of \$130,000.

The pay-rolls of the Comstock mines for the month of November foot up \$122,957.50. Says the Chronicle: The pay-rolls for December will foot up nearly \$190,000 (including the mills). This arises from the fact that a large increase was made in the force employed in the ore producing mines the latter part of November.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

The Debris Question.

EDITORS PRESS:—Perhaps no one thing has transpired within this State since the discovery of gold that has had so depressing an effect upon the interests and welfare of its people as the closing of the principal hydraulic mines by injunction.

Whether that judgment is right or not is not the object of this article. The fact exists that they are closed, to remain closed to some future time, but not for all time. There are too many hundred millions of dollars lying hidden within their bounds, and these millions are soon to be needed. Their want is now being too severely felt in the channels of trade to let them long remain where they are. Whoever can devise a way or means by which hydraulic mining can be again prosecuted as vigorously as it was before litigation commenced will certainly be considered a benefactor. The object of this article is

To Induce Discussion

Upon some proposition whereby all kinds of mining may continue without detriment to the country below, and I call upon all men, no matter whether farmers who are situated in the immediate line of danger, merchants who are interested in the business and prosperity of the whole country, mechanics and day laborers, all of whom are directly or indirectly interested—all that pertains to increase the field of labor.

I would like particularly to see the opinions of civil engineers advanced on the practicality of any plan that may be devised. To all I invite a liberal discussion of the whole matter and a criticism of the plan herein contained. I also call upon the PRESS to give the matter liberal publication, and all with a view that before we, the people of the State of California, decide that hydraulic mining must forever cease, every fair means will be discussed, so we may draw our conclusions intelligently.

If three-fourths of the people of this State could be convinced of the practicability of a plan, and then he satisfied that as a business proposition it would pay, there would be very little difficulty in carrying any such plan to a successful conclusion. What is wanted first is unanimity of action. But to proceed, which I will do in as brief a manner as possible.

To Exemplify My Plan,

I will take the Yuba river for example, and would proceed to erect a dam at a suitable place, where solid bottom could be easily obtained. State Engineer Hall, when acting in the capacity of a State officer, reported on this very proposition (I have not his report at hand). He says, "At a place on the main Yuba, about one-fourth mile below where the South Yuba joins it, there is a splendid site for such a dam, the cliffs on either side being the everlasting granite. That when a dam is raised to the height of between 250 and 300 feet, the waters would not flow over the dam, but would flow across a solid granite ridge into a ravine and pass into the river again at some distance below." He also estimates the cost of such a dam, but I have forgotten the figures. He says that the river above said site is graded at about 50 feet to the mile, and that if a dam were constructed it would grade at about ten feet to the mile above the dam. Thus, every 40 feet would grade up one mile. That the tailings would have the channels of both rivers to fill up, and some of the North fork, which comes in a few miles above. That the capacity of said dam would be equal to holding the tailings from the mines as they were then washing, for 32 years. Suppose that upon a critical examination the above statement was found to be correct. It certainly presents a very eligible site for such a work. Then as for the

Building of the Dam,

I would have the State undertake the work. I would by a unanimous effort of our people try to induce Congress to appropriate \$1,000,000 for the dam. I would place a tax of one per cent on the gross product of all mines whose debris flowed into any stream above said dam, which I believe would yield another million dollars. Then I would have the State locate a branch prison at the dam, and do all the work possible with prison labor, and thereby help to solve another knotty question wherein it is claimed that prison labor should be so used (or even not used at all) as not to come in conflict with other labor. This would be directing it in such a way as to enlarge the field for other labor. I ask that working-men's organizations make note of this, and deliver an expression in the matter.

This then would take us ahead thirty-two years when there will be no more, or so little hydraulic mining on the Yubas, that its tailings would be insignificant. I would provide that the

State Own the Water

Which thus elevated so near the valley, and in the foothills as it were, would be of inestimable value both for irrigating purposes and for power. We would have as it were, a Niagara at our door, whose power could be, and would be, converted into electric power to be transmitted by wire, and used to run our

quartz-mills, factories, and for lighting purposes. I am told that in the New England States a horse power, when caused by water, is estimated to be of the property value of \$1,000.

The Benefits to be Derived

From the starting up of mining and placing it on a permanent basis are manifold, and may well be inferred from the present condition and state of affairs. Since mining has been crippled the gold dollar has very much appreciated in value. It will buy more silver than it used to, and a silver dollar will now purchase more than a gold dollar used to. And the fact of closing the mines has had more to do with it than most people think.

The Gold Product

Of the world is not keeping pace with the increasing demand. Statistics show that it takes a ton of gold each year to fill the teeth of the people of the United States. A ton of gold is worth a fraction over \$6,000,000. No one by-draconic mine in the State ever produced enough in one year to supply the demand for that one purpose. And gold thus used is lost. There are various other uses to which gold is applied, in which the amount so used is lost. It therefore seems to me to be only a question of time when the gold mines must be opened anew to supply the necessary wants of the people, and it is a question whether we will undertake to devise such means or whether we will leave it for future generations.

My opinion is that we had better study the matter very carefully and look at it on all its sides before we come to the conclusion that it must cease.

I think it may be safely estimated that the gold product of the State would be \$5,000,000 more annually than it now is if mines had not been interfered with. That from the time the first trouble commenced has been equal to at least four years of such falling off, which would be equal to \$20,000,000. We will suppose that \$5,000,000 left the State; then we have a void of \$15,000,000.

Would not \$15,000,000 infused into the channels of trade make quite a difference with the people? And henceforth we are to have \$5,000,000 less per year than we otherwise would have, and this to go on for say 20 years. It cannot be said that there are any compensating circumstances to offset this deficiency. On the contrary the exact reverse is the case; during the next 20 years it would be safe to say that \$50,000,000 from outside of the State would come here for investment in our mines, which now will not come. And there will be no more increase in agriculture more than there otherwise would have been, there is or has been no scarcity of agricultural land, and although agriculture has assumed larger proportions and outgrown mining, it has done so in the face of all the damage and destruction caused by mining. The question therefore is not whether farming or mining must cease. Mining might go on indefinitely, and still farming would scarcely be effected. It is authoritatively stated that only one acre in 1000 is liable to damage. I hold to this proposition, that if this State was owned by one person or company,

Mining Would Not Be Discontinued

For the damage done to any or all other interests. To sum the whole matter up, it seems to me that in as much as the general Government by its legislation and encouragement has induced a great many of its people to make large investments in the construction of ditches, reservoirs and tunnels in good faith, that it would be but fair to appropriate a few million dollars to help them out of the difficulty which they are in.

That at this day and age, and in view of the falling off of the production of gold in the world, it is not good policy to shut our gold mines.

That if by an appropriation of \$1,000,000, \$100,000,000 could be liberated, it would be a judicious investment.

That a million from the Government and a million from the mines, with the labor furnished by the State, will construct a dam on the Yuba that will hold the debris for all time.

That the engineering skill of the country thus backed by labor and money, is equal to the building of a dam that will be absolutely safe and last for all time. That the immediate and future benefits to the people of this State will justify the expenditure of the before named units. That what can be done in the Yuba can be done on all the other streams with equally good results. That the whole matter should be thoroughly investigated with a view of how to do it, rather than with a view of how not to do it.

N. CADWALLADER.

San Jose, Cal., Dec. 5, 1885.

Rimini District.

Rimini and Helena Districts, Montana.

[Written for the PRESS by R. G. HUSTON.]

Rimini district is located on Ten Mile creek, some 20 miles west of Helena. It is reached by a stage line run by Messrs. Jurgens & Price who have also a store of general miners' supplies at each end of the road. The first property of note is the Lee Mountain mine, owned by the Consolidated Ten Mile Mining Company, who have three tunnels in on their property. The upper one is in 85 feet, the second one is in 355 feet and the lower one is in 455 feet, and taps the lead nearly 600 feet from the surface.

The width between wall rocks in the lower tunnel is 35 feet, which is, of course, mixed with county rock or it would be one of the largest things on record. They have a large quantity of ore that assays from \$50 to \$60 per ton, and have a concentrator nearly ready to run. With this ore concentrated three or four tons to one it will pay handsomely to ship to Yoston or Wickes for reduction.

The David Stanton is in Red Mountain, and is owned by the same company. They have two tunnels each in 200 feet. At the end of the upper tunnel they have a shaft sunk 70 feet which shows ore all the way down; width of lead four to five feet; character of ore quartz and galena and some zinc blende; average assay 75 ounces silver and 60 to 70 per cent lead.

A number of stock companies have been organized to run tunnels and prospect Red Mountain thoroughly and all have let contracts, and prospecting is being carried on vigorously at this time. Doubtless some of them will develop good mines. The companies are the Red Mountain Tunnel Company, Grand Central Tunnel Co., Narragansett Tunnel Co., Consolidated Company and the Katie Putnam Company. The millionaires in prospect are plenty here. The town of Rimini is located on Ten Mile at the mouth of Beaver creek and was the scene of an immense washout some years ago. Mr. Chessman, proprietor of the water works in Helena, had a large reservoir covering a flat of some 150 acres, with water from six feet to 30 feet in depth. The reservoir broke and precipitated this immense body of water down a narrow gulch and it carried everything before it for miles. Happily Rimini was not built, or many would have lost their lives. As it was, three parties were drowned in the lower gulch.

The Helena District.

On Seven Mile creek, some four miles from town, is attracting some attention just now, and it surely merits it. The Helena mine, now owned by Messrs. Hauser, Holter, Curtin and Forbin, is a promising prospect. The top of this lead was scratched over years ago, and worked in an arastra, but after the top was taken off the ore became hard and could not be worked and made to pay by the old primitive process, and it was abandoned and thought nothing of for years. Finally it fell into the present owners' hands and they put some men to work and have sunk to a depth of 150 feet. They are so well satisfied that they are now letting a contract to sink another 100 feet. If it shows as well as at that depth they will probably put a reduction plant on the mine. Their selected ore from the shaft sold for \$36 per ton. By putting up concentrating works they could make it pay handsome dividends to stockholders. The ledge is irregular, but shows in many places from six to seven feet of ore and one or two feet of pretty high-grade ore on the hanging wall. In the matter of convenience, this mine is unsurpassed, I think, in the world, as you can drive right to it without the usual formality of building a road. Mr. D. M. Sutton, the gentlemanly superintendent of this mine, chaperoned me down the ladder, and through the stoping on the 100 foot level. Then we encountered too much water to go any lower. The company is known as the Helena Silver Mining Company; President, W. B. Raleigh; Vice President, A. M. Hilter; Secretary and Treasurer, J. C. Curtin.

I shall look to hear from the Helena mine as one of the solid developments of the future. There are other mines being developed in this vicinity, one of which has a shaft down 50 feet, and these fortunate prospectors have sold ore enough from that shaft to pay all the expense they have been to, and wages for their time—\$5.00 per day. I am afraid this would induce me to desert the PRESS and go to work on a windlass, for which, no doubt I am more adapted, but all mines or prospects do not turn out so prosperous, yet I think it is a good showing for Helena district.

There is no reasonable doubt that there is a continued mineral belt of different character of ores running through this whole country; and that many fine properties will be developed here within the next decade, is a settled matter in my mind. The developments are many of them miles apart, and for miles there has been no prospecting done, and in some places what has been done was in a crude and unsatisfactory manner.

Spokane Falls.

EDITORS PRESS:—This place is located at the falls on Spokane river and is almost wholly dependent on its agriculture and stock raising for revenue. The farming community here is grumbling, as indeed they are everywhere, at the continued low prices of grain; yet by close economical farming some claim that they can here raise wheat at a profit of fifty cents a bushel, and that is all they can get for it. Oats are here bringing about twenty-five cents per bushel and everything else in proportion. The town claims a population of 1200 and has two large flouring mills. One, the C. & C. Mill, is just new with ten set of rolls and two run of stone, fitted with all the modern improvements. No expense has been spared to make it a first class merchant mill. It is owned and run by Messrs. Clark & Curtis and will no doubt be a success; capacity, 140 barrels per day.

The other, named the Echo Mill, is a very large building and has five set of rolls and one run of stone, and has a capacity of 75 barrels per day. It is the old mill of the place and

makes a fine article of flour. It is owned and run by S. G. Havermale & son.

There are two planing mills in town, both well appointed and seem to be doing a good business.

They are just on the eve of being lighted by electricity, a sixteen-arc light plant being placed there. The Brush dynamo is used and there are about eight hundred incandescent lamps subscribed for in the town. The town is well supplied in all the lines of trade. The California House is the only first-class hotel of the place; it contains seventy-five rooms and is presided over by W. C. Grey who thoroughly understands making his guests comfortable. Two banks are now looking after the financial interest of the community and another is just incorporated with \$75,000 capital.

Nearly all the different secret Orders are represented at this place, and five different churches are organized with buildings of their own. The Methodists and Catholics have each a college building of good size, ample for years to come; so the youth of that portion of Washington Territory need not fail in being "brought up in the way they should go." R. G. HUSTON.

On the Life of Absalom C. Knox.*

[By Rev. J. C. EASTMAN.]

According to the records of Hanover College, where Mr. Knox spent the flower of his life, he was born in Rowan county, North Carolina, April 17, 1820.

His Christian father, who in that day was a slave holder, became dissatisfied with the moral atmosphere of his surroundings and determined to take his family to a State where he could raise them in a spirit of independence. He removed his negroes to the North, and gave to each of them a plot of 10 acres of soil in the region about Cincinnati, while he himself settled with his family at Livonia, in Washington county, Indiana. Here he fell into the parish of that active consecrated minister, Rev. William L. Martyn, afterwards familiarly known over all Southern Indiana as Father Martyn. This minister, from 1818 till 1831, in addition to his ministerial and missionary labors, taught a select school in his own house in Livonia, and he some way inspired his pupils with such an educational and missionary spirit, that perhaps no congregation in Indiana (outside of college towns) furnished more school teachers and more ministers than that congregation in Livonia. The place was but a country village, that by the last census (1880) had a little over 200 people; but it would seem that almost every family in the congregation must have furnished the world with a minister, and many a village and city secured from that fountain its teachers.

The family of the father of Knox were part of this congregation and, doubtless the children were pupils in Mr. Martyn's school, and with their companions drank in the inspiration of the man. The next thing to being a scholar of Mr. Martyn's school was to be a student in Hanover College some 50 miles away.

Hanover had existed for some years as an academy, but about the period of Mr. Martyn's school, it received a charter as a college. And to this college, from its beginning, the Livonia boys were sent to pursue their education.

If there was anyone placed more fitted for kindling religious devotion, and for inspiring them with energy in the varied departments of learning, it was that young college in the then wilderness of Indiana, under the power of consecrated men like Dr. James Blythe, Dr. E. D. McMaster and Dr. Sylvester Scovel, and under the pastorate of Dr. Jno. Finley Crowe.

It was under such influences as these, that Absalom Knox, a lad of 15, fell when about 1835 he entered college at Hanover, and when after some five years be graduated from the classical department in 1840.

In 1840! 45 years ago! In 1840 Texas, New Mexico, Arizona and California formed no part of the territory of the Union. There was not a mile of telegraph in the world; nor an ocean steamer; nor a steam power printing press; nor a sewing machine, nor a telephone.

Since 1840 the world has made strides that we think little of unless we stop to see how fast these days of progress are sweeping us along. Education has much to do with our progress, and among the many worthy institutions Hanover has borne its share of influence, and even still to-day more than ever before, it is doing its noble work. From the address of General W. M. Dunn LL D. at the semi-centennial anniversary, in 1883, we quote this statement:

"Hanover, with her men at work in every field of useful employment, has touched the boundaries of this great land. Her sons are scattered from the shores of the northern lakes to the cotton fields and orange groves bordering the southern gulf. The first rays of the morning sun greet them in their toil among Atlantic cities, and the setting sun throws back her last beams through the Golden Gate on Hanover men."

She has done more than this. In fifty years she has sent her sons to every continent, and her work has girdled the world. Her foreign missionaries are at work in China and India and in Mexico and South America." And we may say that to day from San Diego to Seattle, on these our shores, the streams of Hanover's influence

*This memorial sermon was delivered before the late Mr. Knox's relatives and friends at the Larkin Street Presbyterian Church, Nov. 29, 1885.

ers being poured out to bless the minds and souls of this Pacific Coast. Here and there in city and country, in pulpit and office and professor's chair there are sons of that beloved *alma mater*.

And what has all her host wrought since 1840! As with young men equipped with an education, the next question with this young man of twenty years was—what next? True to the influences moulding his youth he found himself drawn towards teaching and preaching. But which of these to choose? The choice fell in favor of teaching, and for this he was now by nature and training fitted.

Doubtless the greatest influence on earth giving tone and cast to character is that of the mother. Sitting in her domestic sphere, she shapes the plastic forces of childhood, and first of all leads forth the powers of affection, and gives the bias to the moral nature. How to love, and to know right and wrong, are lessons taught in the first brief years of existence; and these first lessons have more to do in giving cast to character than any other ones. Let mothers be loving—let mothers be truthful and just, and the great question of making good men is largely solved.

After the mother, there are a variety of influences contributing towards the formation of character, and the greatest among these is that of the school teacher. The teacher lays his hand upon the growing powers of the intellect, and directs that process by which methods of thinking are formed. Education is not a scheme for examining, but the art of teaching minds how to use themselves. It is a process of training the man to direct the powers of his own mind. It has for its work to give a man an understanding of his mental forces, and to direct and exercise him in their varied movements. This includes, not only a care for the intellect and a culture of the powers of perception, reasoning, judgment, memory and so on, but also a care to train the emotional powers, giving the pupil some knowledge of his natural mental passions and desires, and some experience in self-government, and also a care to train the powers of the will. The education of the will has much to do with the effectiveness of men. It is a serious responsibility to have growing minds committed to one's charge, and the station of teacher is one that is not and cannot be filled by any one who has a spirit of indifference or carelessness. The teacher has so much to do, not only with the proficiency of pupils, but with their efficiency in all their after life. This task, therefore, of shaping so many destinies, is a serious and responsible work.

To this work Mr. Knox gave himself, when at 20 years of age he received his diploma. We find him in 1841-42 teaching at Paris, Illinois, and in 1843 teaching in Franklin county, Kentucky. He must have found himself peculiarly adapted to this pursuit, and must have, indeed, made his mark, for though he gave up this pursuit and entered the Theological Seminary at New Albany, in 1843, as a student for the gospel ministry, at the close of the first year he not only resumed teaching but was elected an instructor in Greek and Latin in the college where he had graduated but four years before. He was manifestly adapted to this high service, for he not only continued eight years in his chair, but with a peculiar power he drew about him and strongly influenced all the students. He lived here among youths who have subsequently become men of eminence in this and other lands. I notice that from the students in Hanover College, who were in his classes from the date of his entrance until he left the institution, 105 entered the gospel ministry, and of these 21 have borne the honorable title of "D. D." A great company have ranked high in medicine, law and literature. Different ones reached the honored seat of Governor in that State and in other States. Not a few have occupied seats in the National House of Representatives and in the Senate, and two have received the vote of the nation for Vice President of the United States. One of these, Thomas A. Hendricks, who graduated in 1841, the year following Mr. Knox, and an intimate college companion of three or four years, has also just finished a worthy career, and his body lies in state to-day in Indiana's capital.

The professors in Hanover College were grand Christian men—moral giants who exercised their powers so well that many generations to come must yet feel the force of their lives through those hundreds disciplined under their moulding hands.

One of the noblest of that number, one who was to Prof. Knox as a loving and generous older brother, was Rev. Prof. S. H. Thompson, Ph. D. L. D., who was for over one-third of a century Professor of Mathematics, and beloved of all the graduating classes. He came to our Golden State in the decline of his strength, and but three years ago—at his ripe three-score and ten—passed away to a joyous reward, and his body was laid to rest on these "sunset shores." With him, and other such men, Prof. Knox lived in that pure moral atmosphere and there showed the youth how they might be men worthy of the name. He had been but one year Professor of Greek when he was honored with the degree of "Master of Arts."

He was not merely a "book-worm," and he was not simply a "professor." In the trying scenes of 1849, when the scourge of Asiatic cholera swept through the land, the college did not escape, many young men died each day, and their instructors cared for them as if they were their own sons. In their visits among the dying boys, on one sad day, Prof. Knox,

going with the noble President, Sylvester Seovel, found his companion stricken with this awful disease, and upheld and almost carried him to his family, where soon he was still in death.

The toils of this season, the excitements of a succeeding religious revival, and the constant press of business were too great for one so sympathetic, and so diligent and earnest, to bear. Under this strain in 1850, both body and mind suffered distressingly. Prof. Knox was now, for the first time, overcome by that nervous disorder which has since annoyed him no little, and which so clouded his comfort and changed the current of his life.

Through this first attack he was kindly housed and nursed by the tender hands of Prof. Thomson and his good wife, and in the course of a few weeks was restored, and resumed his labors.

It was in this succeeding year, at 32 years of age, that he was married in the town of Livonia to Miss Sarah Dollarhide.

This change in his estate suggested new plans, and in 1852, much to the regret of the good people of Hanover, Prof. Knox took his leave of this college and removed to the vicinity of Louisville, Ky., where, with his wife as an assistant, he established a training school, where he might fit boys for college. He continued his teaching for three years longer, but his physical system was undermined, and at last, after 15 years of conscientious and arduous labor, he turned aside from his chosen vocation. He sought relief and health, as so many wisely do, by coming to California, and his life has been prolonged through these years since 1855. But how could he be in any other pursuit what he had been in the loved calling of his choice!

He entered into the cattle business and sought outdoor employment, but ere long a disaster befell him—a disease among cattle ruined his venture and he turned again to a new pursuit.

Back, nearer to his former work, he joined the ranks of the press. For a mind struggling to leave its best impress on its age and times, what was better fitted, after that calling which he could not longer follow than the directing of printing press! What an engine of power is the press!

And how a pure-minded, conscientious man can make it tell for good! In such a land as ours the press is the strongest pillar of our liberties. It is the most potent advocate of the rights of men.

"Here shall the press the people's cause maintain, Unawed by influence, and unbribed by gain—Here patriot truth her glorious precepts draw, Pledged to religion, liberty and law."

We read of a great bishop who, comparing the press among the forces of human potency, gave to it the crown over all, and called it king and it has been written:

"Mightiest of the mighty means
On which the arm of progress leans,
Man's noblest mission to advance
His woes assuage, his weak enhance,
His rights enforce, his wrongs redress,
Mightiest of the mighty is the press."

When, therefore, our brother sought a means of wielding his remaining power for the welfare of men, he chose this. And what it might have been under his management had not disaster overtaken his effort, who can tell?

When men were rushing to the mines, he went up to Virginia City, but he did not stay there very long. Disaster came in roaring flames, and his all was destroyed by fire in 1867. From this he returned to Sacramento. Here, in 1872, came a disaster more dreadful to him and his wife than any that had gone before. They had two sons, Chas. H., who is with us to-day, and Scott, so called for Dr. Scott, our lamented theologian, and one summer day the younger in his play fell into the Sacramento river and was drowned. From this sorrow it would seem the father was never able to recover his wonted spirits. He felt the earth was gloomy and cold. Home, with this jewel gone, could not be what it had been, and his great grief made him often melancholy. And who could help to hear his troubles? He would not share them; he could, or would not shake them off. And now, from the cholera days of 1849, trouble upon trouble had fallen upon him, and trying to hear it, who can wonder if sometimes he was overborne?

He finally entered the employ of Messrs. Dewey & Co. of this city as agent for their house. And in this, notwithstanding his burden of trouble, he has, up to this time of his sad death, done excellent work.

Mr. Dewey says:

"I have never in my business experience known a man who was more mathematically exact, and more scrupulously honest."

One of his associates says: "He was a man of peculiarly logical mind; he was a great reader, but read a class of books that few men care to read—books of philosophy, books of abstruse reasoning. And when he had read, his reception and digestion of the matter was such that in a few lucid sentences he could communicate the drift of the work."

He has done good service in the matters in which he was employed, and many citizens of California have realized solid benefits through his connection with the MINING AND SCIENTIFIC PRESS and *Pacific Rural Press*.

His death was sad, in that it occurred away from home during a business journey, such as he was accustomed to take. He had felt some apprehension when he went away, but he had not been long away when he became sick, and

when, without proper medical counsel he found his expedients unavailing he rapidly succumbed. His surviving son, now residing at San Luis Obispo, reached his bedside at Lone Pine, Inyo county, and was with him in the final hour. He died on Friday, the 20th inst., and although it was designed that the burial should take place in San Francisco, yet, through the inaccessibility of this place and lack of facilities at Lone Pine for the removal of the body, he was buried there.

Thus has lived and died a man, at whose departure many loving friends and many noble hearts throughout the world will mourn.

And we may well join to pay a just tribute of respect to one who here, through 65 years, such a heart, such an intellect, such a conscience. May we all direct our own energies as well.

Experiments in Roasting and Amalgamation.

(Continued from our last issue.)

No. 7.—This same ore as in No. 6 was treated in this experiment. But, in place of quicksilver pure silver amalgam was added (a piece the size of a pea) and the charge ground for two hours. Then quicksilver was added and amalgamated one-half hour longer, to collect the amalgam, before setting was commenced. Value of ore 0.800 oz. gold per ton. Extracted in F. M. 0.620 oz. gold, or 77.5 per cent. Extracted in C. M. 0.565 oz. gold, or 70.6 per cent. The silver-amalgam in the last experiment was moist. In using silver-sulphate was much drier, but by no means hard, the following results were obtained: Extracted in F. M. 0.676 oz. gold per ton, or 84.0 per cent. Extracted in C. M. 0.660 oz. gold per ton, or 82.5 per cent.

No. 8.—Muertos ore, roasted oxidizing. Contained 43 per cent magnetite before, and 19.5 per cent after roasting. This ore was discharged, by mistake, too soon. A considerable part of copper sulphate had remained undecomposed. Two charges were amalgamated, one in the iron mortar with flat bottom, and the other in the wedgewood mortar, both with silver amalgam. Time of amalgamation 2 1/2 hours; then quicksilver added and amalgamated one-half hour longer. Value of ore 0.380 oz. gold per ton. Extracted in F. M. 0.120 oz. gold, or 31.6 per cent. Extracted in W. M. 0.316 oz. gold, or 83.1 per cent. The amalgam from the iron mortar was very base, that from the wedgewood mortar very fine.

No. 9.—Muertos ore, roasted oxidizing. Contained 28 per cent magnetite after roasting. A well-roasted charge, showing not a trace of copper sulphate after discharging. After cooling a slight quantity of copper sulphate was, however, reformed. The amalgamation with silver amalgam was carried out as in previous experiments, but the amalgam squeezed very dry.

Value of ore 0.340 oz. gold per ton. Extracted in F. M. 0.296 oz. gold per ton, or 87.0 per cent; in C. M. 0.286 oz., or 84.1 per cent; in F. M. 0.270 oz., or 79.4 per cent; in W. M. 0.332 oz., or 97.6 per cent; in F. M. 0.292 oz., or 85.9 per cent; in W. M. 0.326 oz., or 95.9.

If the magnetite is ground sufficiently fine it does not interfere with good settler work. In all these experiments no flouing of quicksilver took place, in spite of the grinding, it united without difficulty, and a loss was hardly perceptible.

This amalgam from the charges worked in the iron mortars contained some copper, even if the ore was apparently free from copper sulphate, while the amalgam from the wedgewood mortar was always fine, no matter how much copper sulphate had been left undecomposed in this ore.

Summary of Results.

These results are of great interest and importance, and throw considerable light upon gold amalgamation generally. It has often been found extremely difficult to extract a high percentage of gold from roasted ores by pure amalgamation, and the theory of "rusty gold" has been extensively circulated in metallurgical literature to explain this fact. My experiments lead to the following conclusions:

First.—That the ore should be well roasted in as short a time as possible. The instantaneous roasting in a Stetefeldt furnace will, no doubt, leave the gold in a much more favorable condition for amalgamation than a long continued roasting in a reverberatory furnace. A complete change of the magnetite to ferric oxide is not necessary, and even a large percentage of this mineral may remain unaltered without producing an injurious effect.

Second.—That copper, if it enters the amalgam, even in small quantities, prevents in a great measure the amalgamation of the gold. Lead will, no doubt, act still more injuriously. Hence, the amalgamation in an arastra, where no iron is exposed, will give far superior results than if the process is conducted in an iron pan. Considerable copper sulphate may be present in the ore without materially depressing the result in an arastra.

Third.—The amalgamation of finely divided gold requires friction, and contact alone with quicksilver is not sufficient. But more than that: liquid quicksilver eludes in a great measure the contact with gold, and it is necessary to amalgamate with gold amalgam (for which silver amalgam was substituted in my experiments, and should be in starting works on a large scale). This amalgam should not be too soft, so that in the process of grinding, liquid quicksilver is not pressed out. I have repeatedly drawn attention to the fact that in amal-

gamation generally great fineness of the material treated is injurious, and need only to point out this difficulty experienced in working raw slimes, or the fine dust from roasted silver ores.

Fourth.—Other conditions being equal, the result of amalgamation depends upon the grinding efficiency of the apparatus used. The much better yield in the iron mortar with flat bottom, as compared with the iron mortar with concave bottom, demonstrates this clearly. In grinding effect the wedgewood mortar was about equal to the iron mortar with concave bottom; but in spite of this, it always yielded higher results than the best grinding iron mortar. Hence, the arastra is, under all circumstances, the best amalgamator. It is hardly necessary to state that the arastra must be so constructed that iron does not come in contact with this ore.

Fifth.—Experiment No. 5 gives exceptional results. They are, however, explained, if we take into consideration the character of the ore treated. This charge, being a product of concentration, contained most of the gold in comparatively coarse particles, which are readily taken up by quicksilver. In this case, too, grinding was essential, and mere mixing gave low results.

Sixth.—These facts throw some light upon the working of the Designollo process. The small quantity of quicksilver reduced from the mercuric chloride, by contact with iron under friction, produces at once solid gold amalgam, and the latter is really the effective reagent. That an arastra, the bottom of which is covered with gold amalgam, is the most effective apparatus for amalgamating gold, has been known to the Mexicans for more than 200 years. I may claim to have re-discovered this fact by scientific research. To my knowledge, no series of experiments has ever been carried out before like that recorded in this report. If the Las Minas ores are roasted in a Stetefeldt furnace, and amalgamated in arastras, there is not the slightest doubt in my mind that from 90 to 95 per cent of the gold can be extracted. Besides, the process is well suited to this country, and the Mexicans understand its manipulation thoroughly.

A Cheerful Outlook.

It is held by those who are close observers that this state of the iron trade affords a safe indicator by which to judge of the general business outlook of the country. This arises chiefly from the fact that iron enters so largely into the requirements of every department of industry. A steady or an increasing demand for iron may, therefore, be expected before any general improvement can be reasonably looked for.

From this point of view, then, we may safely announce that the country is already on the sure road to a return of prosperity. Hence, it was that several months since, Mr. Swank, at the head of the American Iron and Steel Association, expressed an official opinion that the country was then on the verge of a change for the better. Later events have fully confirmed that early expression. Moreover, in this improved condition of our iron interests, there is no appearance of any speculative manipulation.

The improvement was first felt in the increased prosperity of the railroad transportation business and in railroad construction as well. The carrying business of the railways reflects the trade movements generally, and is not confined to any one branch of business. It is, therefore, gratifying to note a decided improvement in this direction.

The revival of business is not confined to this country alone. Recent reports from England and the continental States indicate renewed and hopeful activity in commerce, manufactures and industries everywhere. In these days of rapid communication the people of all civilized countries are generally affected much alike by any given condition of things, and it is hardly possible for one nation to be favorably or unfavorably affected without finding a similar condition among all other nations.

Among the cheering signs of the times is the starting up of various manufactures which have long been partially or wholly at a standstill. Many new establishments are also in process of construction or contemplation. This starting up of factories and lighting of unused forge and furnace fires means employment for thousands of now idle men, and prosperity for the million everywhere.

Capitalists who for many months—years, in fact—have been dabbling in stocks and manipulating rings, for want of ought else to do, are now turning their attention to something more substantial—something permanent, and which will tend to utility instead of waste, and give employment to idle hands.

In our own State the late honteous rains will prove a bonanza, which will have a wide and most generous distribution. They have assured full harvests and a generous yield of the precious metal. They have proved the last factor needed to restore confidence throughout the entire Pacific Coast. There is now scarce room for a doubt of a prosperous season in mining, agriculture, trade, commerce and the industries generally. Peace, rest and prosperity are in store for all.

The new Alton gold and silver mining district on the east side of the south fork of the Salmon river is exciting some attention.

TABLE OF CONTENTS.

EDITORIALS.—A Kern County Mine; Academy of Sciences; Baker's Quicksilver Feeding Machine; A New Draft Regulator; Trying a Debris Dam; Mechanics' Institute, 385. Passing Events; Extent of Hydraulic and Drift Mines; Revival of California Gold Mining; Trying New Plans for Cable Roads; Foundry Notes, 388. Lead Smelting, No. 2; The President's Message, 389.

ILLUSTRATIONS.—Improved Draft Regulator for Grates; Quicksilver Feeder for Quartz Mills, 384. Circular Furnace for Smelting Auriferous Lead Ores, 389.

CORRESPONDENCE.—The Debris Question; Rimini District; Spokane Falls, 386.

MECHANICAL PROGRESS.—Inventors Should Study Technicalities; Tool Dressing; English Sheet Makers Won't Have Steel; Superheated Steam; Steam Boilers Become Brittle by Use; Midget Locomotives; Keep Your Fire Surface Clean, 390.

SCIENTIFIC PROGRESS.—The Possibilities of Free Life; Artificial Winds; A New Illuminating Agent; Coating Iron with Aluminum; Two Liquids; The New Star in Andromeda; To Measure Belting in the Roll; Silicon and Temperature, 390.

ENGINEERING NOTES.—Extensive Gas Piping Proposition; How the Gauge of a Railway is Changed in a Day; A New Steering Device, 391.

USEFUL INFORMATION.—Protecting the Obelisk; Going Backwards; Wood Industries in Russia; A Valuable Substitute for Wool, 391.

GOOD HEALTH.—Comparative Longevity of Men and Women; Critical Periods of Life; How Artificial Teeth May do Damage; Cocaine a Cure for Sea-Sickness; To Prevent Bleeding at the Nose, 391.

MISCELLANEOUS.—On the Life of Absalom C. Knox, 386. Experiments in Roasting and Amalgamation; A Cheerful Outlook, 387.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, New Mexico, Oregon, and Utah, 392-93.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 396.

Business Announcements.

Passing Events.

Congress has convened and the President's message has been submitted. What there is in the latter document that affects the mining interests is that portion which refers to the silver question, but it does not at all take the miners' view of the matter.

The Department of the Interior is about to take such action with regard to mineral and agricultural land as will restore to the public domain many tracts which have been taken up as agricultural, which, in the original surveys, were designated on the maps as mineral. A decision has recently been rendered by the Supreme Court on the subject of mineral lands, which is also of interest to miners in this connection.

Only a few weeks now remain in which miners may commence their annual assessment work required by the United States laws. Claim owners are at work in all directions doing this work, for those claims on which it is not done are liable to relocation on the 1st day of January.

A VEIN of rich green oil has been struck in the Puente Hills, Los Angeles, from which 150 barrels of oil were taken in two days.

Extent of Hydraulic and Drift Mines.

This river-har claims of this first years of placer mining, which were worked by single miners or small parties, were often but 20 feet in length and of the same width as the channel. This, in some districts where the virgin ground was very rich, was the recognized extent of a location, though in others the unit was somewhat greater, and in certain localities has reached 200 or 300 feet, measured on the length of the deposit. Occasionally the ground was located in square areas, as, for instance, in plots 100 by 100 feet. Great differences existed in the regulations of the various camps, though the tendency in all was to keep the size of individual claims within narrow limits, but the extensive equipment and development of a modern hydraulic mine of importance demands a large area of workable gravel in order to offset the preliminary expenses and give the mine any permanence. When it is considered that a single company may wash upward of 3,000,000 cubic yards of gravel in a single season, it will be seen that to insure continuity of work considerable extent is necessary. Even with deep banks the acre melt rapidly away before the hydraulic nozzles. The North Bloomfield Mining Company, in a run of 342 days, in 1876, washed 2,919,700 cubic yards. The bank was 260 feet deep.

Many of the more important claims in California comprise tracts of over 500 acres each. The Spring Valley, 1215 acres, and Morris Ravine, 1300 acres, in Butte county; Happy Camp, 507 acres, in Del Norte county; Liberty Hill, 554½ acres, and North Bloomfield, 1585 acres, in Nevada county; Gold Run, 500 acres, in Placer county; North Fork, 800 acres, and Plumas, 1355 acres, in Plumas county; Dry Creek, 1332 acres, in Shasta county; La Grange, 1200 acres, in Stanislaus county; Buckeye, 1700 acres, in Lewis and Clark county; Weaver Creek, 600 acres, in Trinity county; and the Golden Rock, 640 acres, in Tuolumne county, are all examples of this class cited by the census statisticians. A still larger number are between 200 and 500 acres in size. In Colorado, Idaho and Dakota the ground is held in large blocks. One mine, the Castle Creek, in Pennington county, Dakota, consists of 88 claims of 300 feet each in length, with a width equal to the deposit.

Some of the drift mines of Sierra county, in this State, are of great extent. The Bald Mountain mine embraces 7500 linear feet of the channel; the Union, 2400 feet; Hawkeye, 800 feet; Pittsburg, 860 feet; Monumental, 1040 feet; and Empire, 1560 feet. Mr. W. A. Skidmore states that the working life of a mine of this class has a duration of from 10 to 20 years according to length of its location on the channel.

Revival of California Gold Mining.

There has just issued from the press of Geo. Spaulding & Co., a book entitled "Gold Mines and Mining in California," and to which we have heretofore referred in the columns of the Press as being in course of preparation. It is a volume of 350 pages, printed in large type, on fine, white paper, and illustrated with cuts of mining scenes, operations and machinery. Containing a description of gold mining in this State, both past and present, with much information of a practical kind, this book, while useful to the millman and miner, cannot fail to be of interest to the general public. Taking up the subject of gold mining in California at the beginning, the writer traces it down through its entire history, each branch of the business being treated of in detail. While no sudden growth of this industry is predicted, it is shown that the increased hullion production that has already commenced in this State may be expected to continue for many years to come, adding to the population of the mining regions and stimulating all our other industries. The opinion is expressed that with proper encouragement the annual output of gold might be enlarged, until it amounts to several millions more than at present, a condition of things that would tend to restore to California much of her ancient *gloria* and bring to her people great prosperity. Without indulging in any extravagant statements, the author shows very clearly that gold mining in California has been too much neglected, and that our people would find it greatly to their interest to pay increased attention to the business hereafter. The spirit of the book is at the same time conservative; no extreme views find-

ing any where expression in it. A large circulation of this work could not fail to greatly benefit California.

Trying New Plans for Cable Roads.

It is somewhat amusing to see the eagerness with which a certain class of people in the East take hold of the cable railroad system which we have in use in this city, and which originated here, and evolve from it new plans which are to entirely set aside and displace the principles learned from experience. They come out here, learn what details they can, admire and praise our roads, and return home and tell their people that we do not know anything about cable roads, but that they have plans which will eclipse ours. Then they get up a company, sell stock, and perhaps build a section of road. It is for this reason that several roads have been failures, those entrusted with carrying out the details having put in untried plans of their own. The only thing accomplished is an evasion of the existing patents and a big bill of expense for trying experiments. And many times these experiments have before been tried by our engineers here and the plans abandoned. One of the first things that has to be done, however, is to convince the investors that the San Francisco cable roads are crude and dangerous, and that the new plans are great improvements. This is easily done where the people know nothing of these roads.

The latest case of this kind is that of the North Hudson County Railroad Company, who own the principal horse car lines in Hoboken and on the adjacent heights. They have built an *elevated* cable railroad from the ferry at Hoboken to the top of the Palisades. Mr. John J. Endres is the engineer, and he visited this city some time since to see our roads, at which time he had no idea at all of a cable road, and spoke in the highest terms of those he saw here, frilly making up his mind to use the California patents. Since his return, however, he has experienced a turn of mind. Now he says: "It is notorious that in San Francisco the numerous and excessively steep hills left no option. It was cable road or no road. But though the papers of the Pacific Slope have given long accounts of the successful features of the system inaugurated in San Francisco, nothing was said of the loss of life and the long delays owing to stranding of this cable which have marked the career of every cable road in that city. The cable roads of Chicago accomplish infinitely more than those of the Golden Gate city, but the same loss of life and the same delays, owing to the same cause, have also been noted there. An unpleasant feature in the San Francisco grip is that it gives a most terrible jerk at starting, and this is due to the manner in which the jaws of the grip seize upon the cable."

It will be new to most people here to learn that there have been long delays from stranding of cables. Cables have broken, and a few hours' delay have occurred, but this has been so seldom that it is of no moment. There is no doubt that in a single horse-car line in New York more people are killed or wounded than by all the cable roads in this city.

Mr. Endres adopts a cable grip which gradually compresses the cable, and he has some other plane which he has ingrafted on this road he has built. As to their success we can tell better after they have worked for awhile. The jerk at starting the cars is only the case when the gripmen are careless or inexperienced; and Mr. Endres' gradual compression idea will be apt to be "rough on the rope," and expensive. Mr. Endres thinks that even the Brooklyn bridge road is better than ours here; but that runs in a roadway of its own and under different circumstances from crowded streets. He is going to have on his new road a speed of 11 miles an hour, which would be against the law in this city, where the maximum is seven and a half to eight miles. Mr. Endres thinks he has overcome the difficulties attending cable roads in this city, but there is nothing new in this, for we overcame them years ago, and have had seven or eight cable roads running right along and doing work steadily, making money for their owners, and being of great convenience to the public. In this new road the brake and grip are operated together. This plan has invariably been found had and exceedingly dangerous, and was long since given up here for these reasons. It might be good for the owners

of the road to investigate this fact before any accident occurs.

After a few more experiences in equipping roads with untried appliances capitalists will realize that it is better to take the things we have proved to be practical here. As an indication that this feeling is growing it may be said that one of the Eastern roads now built will shortly extend its line, and its managers have written to one of our cable road engineers here to employ him to take charge of the construction of this extension; so that the work will be properly done by a man of experience, they having had enough of experimenting.

Foundry Notes.

The Fulton Iron Works.

The Fulton Iron Works, of this city, which some time since built a tug and passenger boat for the Wilmington Transportation Company, has a contract for building a similar one for the same company. The boat is to be used at San Pedro, Wilmington harbor, the seaport of Los Angeles. She has a length of 104 feet, 21 feet beam and 9 feet 6 inches depth. The engines are compound surface condensing, with high-pressure cylinder of 12 inches in diameter and low-pressure cylinder 22 inches, with 18 inches stroke. There is one cylindrical boiler of 8½ feet diameter, 9 feet 6 inches long. The vessel will be ready for sea by January 15th, and they will commence next week putting in the machinery.

The works have just been shipping considerable sugar machinery for the Sandwich Islands. Among this are two rolls 32 inches in diameter and 72 inches long, with steel shafts 16 inches in diameter. Also four sugar rolls 30 inches in diameter and 60 inches long. The shafts, gearing, etc., go with the rolls.

They are building refrigerating machinery for different orders; one plant is for the Philadelphia brewery, of Los Angeles, to be driven with a Corliss engine 14x24, and a boiler 54 inches by 16 feet. Another refrigerating plant is being made for Merry, Faull & Co.'s packing house, in this city. The boiler for this is 48 inches by 16 feet.

The Fulton Works have just put in six new boilers, 54 inches in diameter and 16 feet long, for the American Sugar Refinery, of this city. They have just shipped three boilers, 44 inches by 24 feet, for Dolbeer & Carson's saw-mill, on Humboldt bay. They are building a large boiler, 11 feet six inches in diameter and 10 feet six inches long, for a new tug-boat belonging to the Tacoma Steam Navigation Company, at Tacoma, W. T. A steel boiler, 48 inches in diameter and 16 feet long, is being built for the steamer Clara Crow owned by the San Joaquin Improvement Company, at Stockton.

They shipped this week to a mine in Mexico two large sized Huntington quartz mills. Mr. Shattuck, owner of the well-known Eagle Bird mine, in this State, owns the mine, and having four or five of the Huntington mills in use here, has ordered them for his mine in Mexico.

SUCCESSFUL.—The clean up of the Bald Mountain Extension Company, at Forest city, Sierra county, for six days, was 320 ounces, equal to \$6452, the gravel averaging five dollars per carload. This, with the yield of 326 ounces of gold for the previous week, and 183½ ounces for the first week of the month, makes a handsome gold yield for the month of November of 829½ ounces or 69 pounds 1½ ounces, equal to \$16,928.70. On November 30th the Board of Directors declared a dividend of 10 cents per share, aggregating \$6000. This is the first dividend, but after this they are expected to follow regularly every month. The Extension stock is steadily advancing in value, and the fortunate owners are heartily congratulated over their reward after years of patient waiting and heavy assessments. Most of the stockholders are pioneer residents of Downieville.

IN THE Piru district, Los Angeles county, the recent rainfall was enormous. The placer miners are jubilant. A large number of placers are being opened, and the copious rainfall will give ample water for washing the rich banks and bottoms of the gold-bearing canyons of Ventura and Los Angeles counties. A largely increased product of gold will be the result for the coming year. In addition to placer mining, there will be a mill put up on Lockwood creek, by Messrs. Woodson and Aram.

Lead Smelting—No. 2.

Last week we gave a detailed description of the rectangular furnaces used in smelting argentiferous lead at Leadville. The engraving on this page shows a furnace with a circular, horizontal section, on the same scale as the rectangular furnace given last week, and a comparison will show that the general principles governing the construction are the same in both. A main point of difference is in the anchoring, which in the square furnace is necessarily effected by bars *D, Q*, while the same object is more conveniently attained, when the section is circular, by a shell of sheet iron *J*, composed of plates about a quarter of an inch in thickness. The diameter of round furnaces at the tuyere level is from 33 to 48 inches, and the capacity varies with this dimension.

Dust Chambers.

The appliances for catching flue-dust in the Leadville smelting works are generally very imperfect, but the reproach does not apply to Leadville alone, for, however extensive the system employed elsewhere, it fails to accomplish its purpose completely. It is said that some English lead works have dust-chambers no less than 5 miles in length, and yet fail to recover all the dust carried from the furnaces; some of the Leadville works, however, make no attempt to collect the flue-dust, a practice unworthy of imitation. The ordinary provision consists of brick chambers on or below the charging-floor, either divided into sections by walls and curtains or not. One such chamber is 75 feet long, 25 feet wide, and 15 feet in height, and another of the same length is only 4 feet wide and six feet high. The dust-chambers are sometimes built of iron instead of brick, and the circuitous direction given to the current by the interposition of walls and curtains in brick chambers is then often obtained by the use of adjoining vertical cylinders, the air and fumes entering the bottom of one and the top of the next.

Blast-Engines.

The blowing engines employed are most commonly of the Baker rotary pattern, though at one establishment the Root blower is in use. The pressure of the blast furnished by these blowers varies from half an inch to $1\frac{1}{2}$ inches of mercury, or say from one-fourth to three-fourths of a pound per square inch, the most usual tension being 1 inch of mercury, or about half a pound per square inch. Where several blowers are employed in furnishing blasts to more than one furnace the pressure is equalized, and the probability of an interference with the work through the stoppage of a blower is decreased by connecting them all with the same main blast-pipe.

The iron work of the furnaces is sometimes made by Denver firms, but usually the entire plant is ordered from the East.

Bartlett Filter.

An experiment was made at one of the works with this arrangement for collecting flue-dust which gave some interesting results. The fol-

lowing is condensed from Mr. Guyard's description: The stack of one of the square furnaces was connected with a Sturtevant fan by means of a sheet-iron flue, through which the fumes were drawn from the furnace and blown through a sheet-iron pipe 150 feet in length which was connected, by means of two branch pipes, with two boxes of thin sheet-iron. The dust was collected in the sheet-iron pipe as in an ordinary flue. Each branch pipe was provided with a damper, or valve, similar to those used in stovepipes, so that the fumes could be distributed to one or both of the boxes at pleasure. Each box consisted of a dust-chamber and a

opened and a light wood fire is kindled. The soot soon catches fire and burns off, leaving the dust white. During a run of five days 3030 pounds of calcined dust were caught in a Bartlett filter from one furnace. The experiment was not entirely satisfactory, owing to defects in the manner in which it was carried out; but the defect was one of arrangement, and by no means inherent in the filter. The furnace was worked without closing the feed-hole, as with an ordinary dust-chamber. The Sturtevant fan consequently drew in as much air as smoke, so that the chamber of the furnace had to be left half open, and about half the smoke escaped

CIRCULAR FURNACE FOR SMELTING AURIFEROUS LEAD ORES.

lowing is condensed from Mr. Guyard's description: The stack of one of the square furnaces was connected with a Sturtevant fan by means of a sheet-iron flue, through which the fumes were drawn from the furnace and blown through a sheet-iron pipe 150 feet in length which was connected, by means of two branch pipes, with two boxes of thin sheet-iron. The dust was collected in the sheet-iron pipe as in an ordinary flue. Each branch pipe was provided with a damper, or valve, similar to those used in stovepipes, so that the fumes could be distributed to one or both of the boxes at pleasure. Each box consisted of a dust-chamber and a

directly into the open air. The use of this arrangement was abandoned by the owners of the works partly on account of the expense involved and partly, as stated by them, on account of the large percentage of arsenic (15 to 20 per cent.) in the condensed matter and its low tenor in silver. As Mr. Guyard, in his analysis of this substance, found extremely little arsenic and much lead, chiefly combined with phosphoric acid, chlorine, and bromine, it is difficult to imagine on what ground the presence of arsenic in such quantity could be inferred. Mr. Guyard's analysis is supported by the fact that arsenic is present to but small extent throughout the district, while phosphoric acid exists in large quantities in many of the ores.

The shipments of Carbonado coal from Tacoma were 9000 tons for November, a considerable falling off as compared with former seasons,

The President's Message.

The President's message is too long a document for us to give entire, and can scarcely be summarized properly. For this coast, the principal questions referred to are those concerning silver and the Chinese. The President intimates that he is not opposed to restriction acts against the Chinese, and will earnestly consider anything Congress may offer to perfect the present laws. At the same time he regrets the "lawlessness" which recently occurred in Wyoming and Washington Territories.

As to silver coinage, the President, much to the regret of the mining community, strongly recommends that it cease. That subject is more fully treated than any other in the whole message. He states that a special effort has been made by the Secretary of the Treasury to increase the amount of silver coin in circulation, but it has soon returned to the Treasury in payment of duties. He also refers to the attitude of other Governments on the silver question, noting it as a significant fact "that four of the five countries composing the Latin Union mentioned in our Coinage Act, embarrassed with their silver currency, have just completed an agreement among themselves that no more silver shall be coined by their respective Governments, and that such as has already been coined and in circulation shall be redeemed in gold by the country of its coinage. The resort to this expedient by these countries may well arrest the attention of those who suppose that we can succeed without shock or injury in the attempt to circulate upon its merits all the silver we may coin under the provisions of our Silver Coinage Act."

THE LATE A. C. KNOX.—In another column will be found a memorial of the late A. C. Knox, which was read before his relatives and friends by Rev. Dr. Eastman, at the Larkin Street Presbyterian Church. In this connection it is proper to mention the kindness and good feeling shown by Mr. and Mrs. Stewart, of Lone Pine, Inyo county, towards the stranger in their midst, they having given the sufferer the best of care during his last illness. Everything they could do was done to make Mr. Knox comfortable and they deserve the hearty thanks of his friends for their kind actions.

THE annual report of the Chamber of Commerce shows a falling off in the foreign trade of New York during the year, compared with that of last year, of over \$97,000,000. The falling off at all the ports of the United States within the same period is but \$107,580,000.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING DECEMBER 1, 1885.

- 331,269.—ELEVATOR SAFETY CATCH—H. Albert, Crescent City, Cal.
- 331,383.—MIXED PAINT—H. C. Dort, S. F.
- 331,491.—DOVETAILING MACHINE—L. P. Garcia, S. F.
- 331,704.—VEHICLE TIRE, ETC.—A. Housner, Taylor, Nev.
- 331,500.—TILE SECTIONS—W. F. Higgins, S. F.
- 331,503.—GANG PLOW—D. M. Johnson, Stockton, Cal.
- 331,307.—FEED WATER HEATER—Dan'l Lee, Sacramento, Cal.
- 331,522.—DEVICE FOR LOCKING COLLARS AND RINGS TO SHAFTS—C. Meese, Oakland, Cal.
- 331,730.—PLANING MACHINE—G. V. Orton, S. F.
- 331,326.—LINK FOR CHAINS—J. P. Preston, Bisbee, A. T.
- 331,547.—SEED SOWER—F. Reyner, Lathrop, Cal.
- 331,336.—LIFT HANDLE FOR SASHES—W. F. Smith, S. F.
- 331,456.—PIPE TONGS—H. F. W. Sohst, S. F.
- 331,347.—BRAKE SHOE—S. Uren, Sacramento, Cal.
- 331,538.—SEEDER, ROLLER, ETC.—Walker & Barlow, Portland, Or.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by telegraph or otherwise), at the lowest rates. American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

MECHANICAL PROGRESS.

Inventors Should Study Technicalities.

Inventors, as a class, do not study the laws of mechanics systematically.

It is frequently amusing to see the complication of cogs, ratchets and wheels found in machines, which have but a simple duty to perform.

Those who have studied machinery and have contributed inventions, can best appreciate how much more simple they can arrange the movements for performing a given duty after they have had several years of practice.

Practice is but another name for education, and why not substitute much of the time spent blundering around in the dark without the light of knowledge, for good books containing the results of the practice of other men in whatever art or science you desire to study.

It is much easier to read in a book and thoroughly understand, too, the best principles upon which epicycloidal cog gearing is constructed than it is to rediscover those principles; and this you would have to do, or find an equivalent, before you could possibly make a success in this line.

For another instance, the study of calorifics, as applied to the development of power in an ordinary steam engine: thousands of engines are running in this country, every day, wasting unnecessary quantities of fuel, variable clap traps in every particular, the result of the difference between what some engine builders actually know and what they ought to know.

Young men who have a life time before them, without the means to take a regular technical course, can find in any good library every principle that is necessary to make a systematic beginning. Special books can then be bought or borrowed, and in addition, scientific papers and periodicals can be obtained by any one, if he will exert himself with a fixed determination to be somebody, and not be an "it" in the world's great work.

Life is a serious matter, and those who have health and strength should be certain that not a day passes without they have learned something new that is of real value to add to their stock of good things, which, probably, some day they will ask the world to buy, when quality will be considered rather than quantity. So, then, young inventor, young mechanic, if you have been exercising your mind only upon the pictures of hope, you must

"Be up and doing.

With a heart for any fate,
Still achieving, still pursuing,
Learn to labor and to wait."

—American Inventor.

Tool Dressing.

There are few jobs in the machine shop that make so much general annoyance as that of tool dressing. The machinist has his own personal notion of the style and shape, the hardening and temper of the tool he uses, and the tool dresser in the smithy must ignore all his experience and observation, for the time being, to cater to the machinist's whim. In short the forger becomes only a helper to the fancy of the machinist. On the other hand, the machinist has frequently to encounter the obstinate peculiarities of the forger, who insists on teaching the machinist about work he alone understands. Good forgers dislike the job of tool dressing because of its annoyance, and so it frequently happens that the work is handed about in the smith shop until it rests at last with the least careful man. Some machinists also insist in dahlbing at the forge and greatly annoy the smith by their meddling. Indeed, this interference is often carried much too far for the benefit of good order, proper work and reasonable profit. It is too much the custom to consider the tool dresser as a man at call for the machinist, and where every lathe and planer hand has his own notion they make it somewhat lively for the smith.

Often to such an extent is this personal whim carried that there are few machine shops where there is a uniformity in shape of alterable tools; at every lathe and planer these tools differ in form or vary in temper—the workman is known by this peculiarity as much as by his personal name. There is no proper reason why this should be, any more than each workman should alter the size and change the shape of rule or gauge. There are determinate and exact forms for turning and planing tools adapted to cast-iron, wrought-iron, steel and brass, and these forms, once ascertained should be kept and used as standards for the shop. Models of tools should be kept for exemplars and no departure from these should be allowed except for special cause and for particular work.

One of the most common faults with the ordinary turning and planing tools in use in our machine shops is the excessive clearance; they are not made and ground to the right angle to keep down to the work, but are so constructed that this point and cutting edge alone offer resistance, as well as alone do the cutting. There is no sense in this, except that with a tool so constructed the workman can plow and gouge, and dig, and make a great pretense of work, and then blame the iron in the casting and the iron in the shaft for the irregularities of surface when it comes from planer or lathe. The cutting portion—point or edge—of a tool for such rigid material as iron or steel should

be as nearly on the moving plans of the work as possible, and the heel of the planer tool should be raised as slightly as possible above the level of the cutting point. To be sure, such a construction necessitates more frequent grinding, perhaps, when the work is rough and demanding, but it gives better results, and when there is after finishing to be done it will pay the proprietor, if it does not please the piece operator.

ENGLISH SHEET MAKERS WON'T HAVE STEEL.—The advantage of steel instead of iron for tin plates is now universally acknowledged by all who use that material. It is a manufacture now almost altogether confined to England, twenty or thirty million dollars worth being annually imported into this country. The English makers of ordinary sheets for merchant and galvanizing purposes won't have steel. They decline steelmasters' offers to supply blooms and billets at easy prices for rolling down in the iron mills. It is cheaper, they declare, and answers their purpose much better, to continue to make sheets out of puddled iron.

One important reason for the adherence to puddled iron is that rolling down from steel blooms would at once mean a large diminution, in some cases nearly one-half, in the amount of work which the mills could get through in a given time.

The largest portion of sheet worked up in this country is manufactured into cans for putting up fruit, meats, etc., for which purposes steel has a very marked advantage, and costs but a trifle if any more. The best solution of the question would seem to be the establishment of works for this manufacture in this country. A slight increase in the present tariff on sheet tin would enable the business to be profitably carried on in this country, and save to our producers the enormous sum of about thirty millions of dollars annually. This foolish move on the part of English sheet makers ought also to give a further impetus to this establishment in this country of this important and rapidly increasing business.

SUPERHEATED STEAM.—It is believed by many (and some technical papers insist upon it) that superheating steam increases its pressure in pounds. This, says the *Mechanical Engineer*, is incorrect. If the steam is ordinarily dry, superheating to any temperature does not increase the pressure one ounce. In steam engines, steam superheated slightly is economical, in that it maintains its normal temperature longer; that is to say, it does not condense so quickly, by reason of having a margin of heat above that due to its pressure, but highly superheated steam has disadvantages which are not counterbalanced. It affects fibrous packings, decomposes lubricants, attacks working surfaces, by drying them off so that they are apt to cut, and it has a special affinity for rusted surfaces, increasing and expediting the destruction of parts so affected most rapidly. From the instant that steam leaves the vessel in which it is generated, it commences to deteriorate in value, by loss of heat. The further it goes before reaching its work, the more it loses, and the only office that superheating can fill is to support the vitality of steam and reinforce it. No other work has yet been discovered for it in steam engines.

STEAM BOILERS BECOME BRITTLE BY USE.—Peter Carmichael recently read a paper upon steam boilers before the Scotch Institution of Engineers, in the course of which he mentioned that it had been found that "all qualities of iron get hard and brittle after the boilers have been at work more than a dozen years, more especially where exposed to the action of the fire; and that in the furnaces, even Lowmoor iron becomes as brittle as common iron in that time, and great care has to be taken in making repairs to prevent the plates from cracking. For this reason 16 to 17 years is long enough for a boiler to be in use, at a pressure of 40 pounds to 45 pounds. If used longer, the pressure ought to be lowered." Two boilers which had been in use 19 years, and which required repairs, were found by Mr. Carmichael so brittle that the rivet heads on the outside flew off when the inside heads were struck, showing that the rivets had deteriorated as much as the plates.

MIDGET LOCOMOTIVES.—The field of usefulness for the locomotive and iron rail is constantly being enlarged. "Midget locomotives" for plantation use are now said to be superseding mules. One of them weighs only three tons, and they are used on rails which weigh 12 pounds to the yard. The cylinders are only 10 inches long. These little engines are not confined to wood for fuel. As lumbermen, they burn wood. As plantation engines, they frequently burn refuse sugar cane. In a different form, but with the same diminutive cylinders, they are used in coal mines for hauling cars, and run either soft or hard coal or coke. In their smallest sizes they are only 10 feet long over all, 4½ feet high and 5 feet wide. A few bushels of coal and a few pails of water kept them running all day. One of these mules in a coal mine at Brookfield, Ohio, pulls 20 cars, weighing nearly three quarters of a ton each, up a grade 1360 yards long that rises at the rate of 105 feet to the mile.

KEEP YOUR FIRE SURFACE CLEAN.—Particular care should be taken to keep sheets and parts of boilers exposed to the fire perfectly clean.

SCIENTIFIC PROGRESS.

The Possibilities of Frog Life.

Some of our exchanges have recently been discussing the possibilities of frog life. The discussion arose from a query addressed to the editor of the *Manufacturer and Builder*, which was referred to Prof. Leidy, of the University of Pennsylvania. The Professor in his reply says: "The stories of toads, etc., living enclosed in the most ancient rocks, is simply absurd, and I get out of patience seeing them so constantly repeated by editors and others who ought to know better. The conditions, or laws, of life are well understood, and unless they are in constant 'play' life cannot exist. An incessant supply of nutriment, moisture, air, and a certain range of temperature are necessary. Without these the plant or animal is soon exhausted. Some animals may live two or three years at most, but are then worn out and die. What must of necessity follow if a toad breathes and acts without food? Can it hurn forever! The persons who tell such stories are either liars or incapable of observation.

A United States' senator once gave to Prof. Henry a supposed parasite, which he thought to be a centipede, and reported that he had seen his son vomit the creature, and had afterwards seen it squirm on the floor. It was submitted to me for information and name, and it proved to be a segment of an orange.

A century ago the French Academy appointed a committee to investigate the toad matter. The committee made experiments by enclosing toads in holes bored in soapstone, plugged with wood. After a few weeks or months the animals were invariably found dead. Only think of a toad in a marine rock, or in any ancient rock, in which all the fossils of these rocks are of extinct forms, while the living toad proves to be a modern species!"

If toads and frogs found in cretaceous rocks had been there from their formation it would be equivalent to saying that the live frog could be ages and ages older than its fossil relative. Such a declaration would be the height of absurdity. If thoroughly inquired into, it would probably be discovered that in each case there was a fissure in the rocks or trees in which frogs have been found large enough for the admission of water and the embryo frog which has developed there. It has been assumed by some that the frog naturally contains an acid, which by chemical action on the stone provides that the space of the frog's disposal shall be as large as its body. A second hypothesis is that not the egg but the primary frog, scarcely larger than the egg itself, falls into the rock or tree and continues to grow, deriving air and food in the form of small insects from the water that penetrates to its abode. Certain it is that frogs when artificially secured in air-tight and water-tight vessels speedily die. Experiments made by members of the French Academy a century ago proved this. Early in the present century Milne Edwards enclosed frogs in vessels made impervious to air, and the creatures speedily perished. Three frogs were once enclosed in a close box for eighteen months, at the end of which time one was dead and the others in a dying condition. Dr. Macartney hurried a toad in a vessel covered with a slate about a foot deep in the ground. At the end of a fortnight it seemed well and as plump as before. When, however, he enclosed the same toad in an air-tight vessel and buried it, it soon died, and at the end of a week was much decayed.

Dr. Buckland made some experiments which are claimed as conclusive. He placed 12 toads separately in 12 holes cut in blocks of hard flinty sandstone. They were firmly sealed in. The imprisoned animals were buried three feet deep on November 26, 1825. At the same time, four toads were deposited in holes cut in the heart of an apple tree and the opening securely plugged. Four others were also placed in plaster-of-paris covered with luting. On Dec. 10, 1826, all the buried toads were examined. All in the hard stone and in the tree, and two in the plaster-of-paris were dead. The remainder were dying; but some placed in a softer stone were in tolerably good health, and some were actually fatter than when placed in the holes. From this it would appear that in positions where water can penetrate, frogs may live, and even thrive, although buried at a considerable depth, entirely away from the light and any visible means of subsistence.

THE NATIONAL ACADEMY OF SCIENCES met at Albany, N. Y., on Nov. 10th, and enjoyed a large and distinguished attendance. During the four days of the session a large number of papers were presented; many of them were of more than ordinary interest. Prof. Young gave a resume of the history of that erratic star in Andromeda. Prof. Pickering's paper on "Stellar Photography" attracted marked attention. After pointing out the great progress which has been made in this department of late years, he cited a recent victory in gaining the impression of stars so distant or so minute as to be beyond the discovery of the most powerful telescope yet constructed. Major Powell's description of the stone ruins on the Colorado and Rio Grande pointed to the conclusion that the arid regions now so characteristic of the interior of the continent were once fertile and well watered. His paper was full of interest. Prof. Graham Bell made a preliminary report on hereditary deafness, having made a careful study of three out of the six branches of the

Lovejoy family, in which there are numerous deaf mutes. Other papers by Prof. Hall, Prof. Newberry, and other well-known members made the session one of much interest.

Artificial Winds.

A novel apparatus has been constructed by M. Rougerie, of Pamiers, France, and brought recently before the French Academy of Sciences. It gives rise to air currents similar to the great winds of the earth's atmosphere. As described in *Engineering*, the apparatus consists of a small artificial terrestrial globe put into rapid rotation in the surrounding air. In fact, it is a miniature of the earth, and by its rapid rotation it gives rise to air currents resembling the trade and other dominant winds of the world. These currents are shown by girouettes placed round the globe at small intervals, like the wind marks on the French marine charts. The apparatus reveals the following facts: The northeast and southeast trades are reproduced, and this equatorial zone of calms caused by their meeting. The gentle breezes from north and south, which disturb the equatorial calms, are also seen. So is the overthrow of the northeast trade in the southwest monsoons in the gulfs of Oman and Bengal. An ascending current in the equatorial regions is shown, and a descending current near the Azores under the center of maximum barometrical pressure of the North Atlantic; also a descending current is indicated between St. Helena and the meridional coast of Africa, under the center of maximum barometric pressure of the South Atlantic. At the poles there is a current descending from the zenith. The southeast trade at the Canaries is represented, while at the same time a south wind blows at the summit of the Peak of Teneriffs. Ascending currents from the east and west over Central America combine with the upper returning current of the northeast trade, thus explaining how the ashes of the volcano of Consequina, on Lake Nicaragua, were transported to Jamaica during the eruption of the 25th of February, 1835. Owing to the defects of construction, the device does not reproduce in a perfect manner the variable winds between the tropic of Cancer and 50° N. lat., nor the corresponding winds between the tropic of Capricorn and 50° S. lat. In the same way the southwest and northwest winds of 50° N. and S. lat. are not very faithfully imitated.

A NEW ILLUMINATING AGENT.—The *Organ fur Oelhandel* gives an account of some experiments lately made in St. Petersburg with pyronaphtha, an illuminating oil which Beilstein, the celebrated Russian chemist, thinks will supersede kerosene. It is said to be wholly free from danger of fire, and burning kerosene is easily extinguished by it. Pyronaphtha itself can be readily put out by water. It burns with a bright light, and gives off no smoke or vapor, while the fact that it is a residual product of the Baku distillation of petroleum makes it cost less than kerosene.

COATING IRON WITH ALUMINUM.—The process of Dr. Gebring of Germany, by which iron is coated with aluminum, is now largely made use of. There is used for the purpose a Bunsen burner with a blast or muffle. By this process it is possible to manufacture various articles of the durable metal for daily use, the coating of aluminum giving them a silver-white lustre. This metal, as is well known, does not oxidize under normal conditions, stands heat of an ordinary fire, and is susceptible of a much higher polish.

TWO LIQUIDS.—Recent experiments have shown that common atmospheric air, in the process of liquefaction by pressure, is separated into two distinct liquids, different in appearance and composition, and the one superimposed upon the other, separated by a well-defined marking. The lower liquid is found to contain 21.23 per cent in volume of oxygen, and the upper one from 17.3 to 18.7 per cent. These liquids remain separate for only a few seconds of time.

THE NEW STAR IN ANDROMEDA.—Prof. Young read an interesting paper before the late meeting of the National Academy of Sciences on the history of the new star in Andromeda, in which he quoted Monck's hypothesis for its luminosity on the ground, that it may be a dark star passing through the nebula and that its light may be due to friction, as meteors, which are small dark bodies, are made brilliant by friction in passing into our atmosphere.

THE NEW METAL GALLIUM melts at 81.1 degrees Fahrenheit, becoming liquid when held in the hand. Its specific gravity is a little less than six, or about half that of lead. It tarnishes but slightly in the air. It adheres readily to glass when fused, forming a beautiful mirror. In chemical characteristics the rare element gallium most resembles the abundant element aluminium.

TO MEASURE BELTING IN THE ROLL.—A simple method, which is very closely correct, is as follows: The sum of the diameters of the roll and the eye in inches, multiplied by the number of turns made by the belt, and this product multiplied by the decimal .1309 will be the length of the belt in feet.

SILICON AND TEMPERATURE.—Two French experimenters make the remarkable report that silicon, though unaffected by a temperature of 2370° F., volatilizes at 824°.

ENGINEERING NOTES.

Extensive Gas Piping Proposition.

The cheapness of natural gas as a fuel renders it a desirable acquisition, but the remoteness of the wells seems at first sight an insuperable obstacle. Nevertheless, it is a fact that companies are being formed by oil capitalists and Eastern manufacturers for the purpose of piping natural gas to seaboard at New York and to the lake cities of the West.

Chimerical as the scheme may at first appear, there are shrewd capitalists who are willing to venture their millions in the enterprise. The National Transit Company are already piping the crude oil 500 miles to refineries. Of course, it has to be forced by pumps. If crude petroleum can be forced 500 miles, it would certainly be much easier to force gas 1000 miles or more.

There is every reason to believe that the supply of gas is inexhaustible. The pressure required to overcome the friction of such long lines would be very great, but relays of pumps, worked by the gas itself, would keep it moving. Gas is a very handy as well as cheap fuel. All that is requisite is to turn a little wheel, apply a match, and your fire is kindled. No more family quarrels as to who shall do the disagreeable thing of kindling the fire. Anybody will do it.

Patents are pending, and many more are incubating, having for their object the utilizing of gas in various ways—for illuminating as well as heating. One party has patents pending for using compressed gas for locomotives. It will be accomplished by tubing and tanks in connection with the tender. Gas transportation tubes would naturally follow the lines of railroads. Nothing easier than to transfer a 20-mile supply of gas from a stationary to a locomotive condenser, in half the time it requires to take in water for the engine, and both operations may be performed at the same time.

HOW THE GAUGE OF A RAILWAY IS CHANGED IN A DAY.—The gauge of the Vicksburg and Meridian Road, 140 miles long, was changed October 22d from five feet to four feet eight and a half inches, by the following program: "Twenty-four gangs of twenty-six men each will work in each gang designated as follows: Six men drawing inside spikes, one man driving down studs, five men throwing rail, three inside spikers, eight outside spikers, three extra men for shoving car, carrying water, etc., making in all 624 hands, will proceed to move the south rail of said road in three and a half inches, thus changing the five-foot gauge to the standard or four feet eight and a half inch gauge. This is a big undertaking, and is one which, under the plans proposed, will necessitate a suspension of all trains on the road from daylight of the 22d inst., until the work is complete. The road will be broken instantaneously in thirteen different places at daylight, and will remain broken until the squads of twenty-six hands can have moved the iron or their respective sections, which vary in length from seven to ten miles. Each gang will be supplied with the following outfit: Twelve spike mauls, ten claw bars, six spike maul handles, one track wrench, one monkey wrench, one adze, one ax, two shovels, two track gauges, eight wooden hand spikes for throwing rail, one barrel water, one water bucket and one tin cup. These tools, together with one day's supply of cooked food, placed on the five-foot push car and taken to the end of the section, where they will commence work on the day of the change. The alternate inside spikes are now being pulled and driven in place and the ties and roadbed leveled for placing the rail, so that on the day of the change all that will be necessary to do will be the pulling of the remaining spikes and sliding in of the rail and spiking it temporarily, to be finished up on the following day."

A NEW STEERING DEVICE.—The St. Louis *Republican* says: Mr. Wm. H. Burns, of St. Louis, has invented a simple and ingenious device for steering steamers. As steamers are now built, the propeller screw is fastened at the end of a rigid shaft, which has the tendency to move a vessel either straight ahead, or straight back, the rudder controlling the direction of the vessel, and acting very gradually, so that one of the large ocean steamers has to travel nearly two miles to turn around. Mr. Burns' invention dispenses with the rudder, and puts in its place a strong iron frame, swinging just like a rudder on an upright shaft, but with the propeller screw mounted in it. This frame can be swung around by the man at the wheel in like manner as a rudder, but when it swings the screw swings with it, and, of course, in so doing changes the direction of its power, so that it no longer pushes the ship directly ahead. For instance, when it is desired to make a quick, sharp turn in the direction in which a ship is moving, the frame like a rudder, is swung around till it stands at right angles with the vessel's keel. The screw continues to revolve, and, of course, its entire force is applied to the work of pushing the stern of the vessel sideways, without contributing anything to the forward motion. The upright shaft on which the frame swings, and which corresponds with a rudder post, is revolved by the ship's engines, and the motion is contributed to the screw by a beveled gearing on its upright shaft, around which the propeller swings with perfect freedom.

USEFUL INFORMATION.

Protecting the Obelisk.

The progress of disintegration of the obelisk recently set up in Central park, New York, has been advancing so rapidly that the park authorities felt that its complete destruction would soon ensue unless some steps were taken to arrest the progress of the damage. After considering various methods which had been proposed to counteract the evil, they finally decided to adopt the method proposed by Mr. R. M. Coffall. This consists in treating the surface, under proper conditions, with a compound composed substantially of paraffine and creosote. The result, it is anticipated, will be the rendering of the surface of the stone proof against the percolation of water, and consequently frost and fungus proof.

The method of applying the preparation consists in first carefully going over the surface of the obelisk and removing with scraping instruments all loose fragments, chips and fungoid growths, then warming the cleaned surface with the aid of portable heaters, and applying to the warmed surface the melted compound. This operation is to be repeated until the stone has absorbed as much of the compound as it will take up, going over the entire surface of the monument in this manner.

The compound of paraffine and creosote is said to be chemically combined through the action of a third substance, in which both are soluble when heated. The name of this third substance is not revealed. The compound does not evaporate, is not affected by extremes of temperature, acids, alkalis, or destructive gases, and is practically imperishable.

The work of treating the obelisk has already been completed, and it is thought by good judges that it will be effective and permanent.

The examination and removal of the scale are said to have revealed the fact that the rapidity of the work of disintegration has been remarkable and had progressed much further than had been supposed. About 1000 pounds of scrapings were removed from the entire surface. Behind nearly every flake appeared a greenish fungoid growth, in addition to the dirt and dust which had found its way behind the scales and into the innumerable minute cracks which appeared upon the surface.

The outcome of the experiment will be watched with much interest. If successful, it will provide a simple and effective method of preserving from destruction many other interesting monuments, works of art and architectural decorations which are rapidly going to decay in almost all parts of the civilized world.

"BOTH" HANDED PEOPLE.—It is supposed to be a great misfortune to be left-handed; but is it not at least a misfortune to be merely right-handed? Why not be both-handed? We do not often realize what a useless and ineffective member this poor left hand of ours is until our right arm is disabled in some way or burdened with a fretful baby who must be held while we want to work. Now if we could only sew or write with the left hand, what a blessing it would be. Then too the right hand may be lost by some accident, when the use of the left hand becomes a prime necessity. Now why not teach children to be both-handed? They naturally use both hands with equal ease, and why should they not be trained to use both with equal facility? It is cruel to try up a child's left hand when he attempts to use it—unless he uses it to the exclusion of his right hand—since it practically maims him for life. Constant use of the right hand makes the right side of the body larger and stronger than the left, which is in itself a reason for not doing so. Let children have the free use of both hands, and encourage them in it. While nearly all machinery and working implements are constructed to be operated with the right hand, there is little enough encouragement for the left hand.

GOING BACKWARDS.—There seems to be an inclination on the part of the Federal Government, just at this time, to make war upon most of the Government bureaus and commissions which have been established to aid and encourage scientific and educational work. We might mention the Geological Survey, the Coast Survey, the Fish Commission and the Educational Bureau. Some reform is undoubtedly needed in these various directions, and retrenchment might probably be applied without any serious injury to the general progress of the work involved; but it is folly to condemn each work entirely because abuses have crept into the conduct of the same. In the mass of criticism which is now being directed at these bureaus and commissions there is undoubtedly some truth. If those in charge, or the friends of scientific progress, were wise they would be prompt in seeking out abuses and proposing such reforms as might be practical and proper, and thereby disarm criticism. The particular way in which reform is practical should be suggested by the friends of science, and not left to those who are incapable of appreciating the value to the country at large of such scientific work as has been taken in hand by the Government.

WOOD INDUSTRIES IN RUSSIA.—Few countries can show better utilization of forest products than Russia, particularly in furnishing industrial employment to the poorer and less skilled class of workmen. The better class of work is

also largely carried on. Carriage and wagon making is said to give almost full employment to the people of not less than 530 villages. It is one of the peculiarities, however, of Russian work in this line, that a vehicle is seldom finished on the spot where it is begun—one village is generally almost exclusively engaged in making spokes, another makes boxes, while a third will make the body, etc. Wooden spoons are an important product of Russia—126,000,000 being turned out there every year. A similar subdivision of labor is seen even in this simple manufacture, as in the case of carriages—one workman cuts the wood into proper lengths, another shapes the spoon in the rough, while a third hollows out the bowl. Spinning wheels form a large branch of manufacture, and a great number of articles in which wood forms the almost exclusive material for manufacture.

A Valuable Substitute For Wool.

The name of "vegetable wool" is applied to a fibrous material obtained from the leaves of the fir, a manufacture for this purpose having been established near Breslau, in Silesia. The species of pine thus operated upon is the *pinus sylvestris*, or wild pine; and it would seem that every member of the pine tribe might be turned to similar account. The leaves of these trees on examination will be found to be made up of a fibrous material held together by a resinous substance. The latter may be dissolved out by means of alkalis, leaving the woolly matter behind. Coverlets, blankets, and other articles made of vegetable wool are in use in Austria, and especially in the public institutions of Vienna. The material is warm, durable, and in all respects agreeable; moreover, it possesses the excellent quality of preserving a certain balsamic and decidedly wholesome smell, which nevertheless is so inimical to insects that they never harbor in it, as they do in almost all the ordinary descriptions of bed material. The resinous matter holding the woolly fibers together—and which is eliminated or dissolved out by the alkalis—is also turned to account, medicinal baths being made with it as a basis, and which are found to be useful in various chronic diseases.

It is stated in the *Augusta (Ga.) Chronicle* that experiments have been made in that city by Major P. H. Langdon with the leaves of the common Southern pine, which have been prepared and woven into a coarse fabric, which is of good texture and handsome appearance.

STEAM that does not carry more than three per cent of water is considered dry steam.

GOOD HEALTH.

Comparative Longevity of Men and Women.

Interesting researches concerning the comparative longevity of men and women in Europe have recently been made by the Director of the Bureau of Statistics at Vienna. From these it appears that about a third more women than men reach advanced age. Women oftener lead quiet, regular lives. They have fewer bad habits, are less exposed to strong passion and excitement. It appears from the gathered statistics of the world that women have a greater tenacity of life than men. Nature worships the female in all its varieties. Among insects, the male perishes at a comparatively early period. In plants, the seminate blossoms die earliest and are produced in the weaker limbs. Female quadrupeds have more endurance than males. In the human race, despite the intellectual and physical strength of man, the woman endures longest, and will bear pain to which the strongest man succumbs. Zymotic diseases are more fatal to males, and more male children die than females. Deverger asserts that the proportion dying suddenly is about 100 women to 780 men; 1080 men in the United States in 1870 committed suicide to 285 women. Intemperance, apoplexy, gout, hydrocephalus, affections of the heart or liver, scrofula, paralysis, are far more fatal to males than females.

Pulmonary consumption, on the other hand, is more deadly to the latter, which argues that we ought to give the girls of our families all the outdoor exercise that they need. Females in cities are more prone to consumption than in the country. All old countries not disturbed by emigration have a majority of females in the population. In royal families the statistics show more daughters than sons. The Hebrew woman is exceptionally long-lived, while the colored man is exceptionally short-lived. Dr. Hough remarks that there are from two to six per cent more males born than females, yet there is more than six per cent excess of females in the living population. The rush and worry of the average business man in this country is apt to make him prematurely old, unless he takes judicious recreation. The females are to a great extent exempt from this overstraining about business cares, which may, in a degree, account for their superior vitality.—*The Indicator*.

CRITICAL PERIODS OF LIFE.—From the age of forty to that of sixty, a man who properly regulates himself may be considered in the prime of life. His matured strength of constitution renders him impervious to the attacks of disease, and all functions are in the highest order. Having gone a year or two past sixty,

however, he arrives at a critical period of existence; the river of death flows before him, and he remains at a standstill. But athwart this river is a viaduct, called "The Turn of Life," which, if crossed in safety, leads to the valley "Old Age," round which the river winds, and then flows beyond, without a boat or causeway to affect its passage. The bridge is, however, constituted of fragile materials, and it depends upon how it is trodden whether it bends or breaks. Gout, apoplexy and other bad characters are also in the vicinity to waylay the traveler and thrust him from the pass; but let him gird up his loins, provide himself with perfect composure. To quote a metaphor, the "turn of life" has a turn either into prolonged walk or into the grave. The system and power having reached their utmost expansion, now begin either to close like flowers at sunset, or break down at once. One injudicious stimulant, a single fatal excitement, may force it beyond its strength, while a careful supply of props at the withdrawal of all that tends to force a plant, will sustain it in beauty and vigor until night has nearly set in.

How Artificial Teeth May Do Damage.

Another agent in the combination to maintain for the man of advancing age his career of flesh-eater is the dentist. Nothing is more common at this period of life than to hear complaints of indigestion experienced, so it is affirmed, because mastication is imperfectly performed for want of teeth. The dentist deftly repairs the defective implements, and the important function of chewing the food can be henceforth performed with comfort. But without any intention to justify a doctrine of final causes, I would point out the significant fact that the disappearance of the masticating powers is mostly coincident with the period of life when that species of food which most requires their action—viz., solid animal fiber—is little if at all required by the individual. It is during the latter third of his career that the softer and lighter foods, such as well cooked cereals, some light mixed animal and vegetable soups, and also fish, for which teeth are hardly necessary, are particularly valuable and appropriate. And the man with imperfect teeth who conforms to nature's demand for a mild non-stimulating dietary in advanced years will mostly be blessed with a better digestion and sounder health than the man who, thanks to his artificial machinery, can eat and does eat as much flesh in quantity and variety as he did in the days of his youth. Far be it from me to undervalue the truly artistic achievements of a clever and experienced dental surgeon, or the comfort which he affords. By all means let us have recourse to his aid when our natural teeth fail, for the purpose of vocal articulation, to say nothing of their relation to personal appearance; on such grounds the artificial substitutes rank among the necessities of life in a civilized community. Only let it be understood that the chief end of teeth, so far as mastication is concerned, has in advancing age been to a great extent accomplished, and that they are now mainly used for the purposes just named. But I cannot help adding that there are some grounds for the belief that those who have throughout life from their earliest years consumed little or no flesh, but have lived on a diet chiefly or wholly vegetarian, will be found to have preserved their teeth longer than those who have always made flesh a prominent part of their daily food.—*Popular Science Monthly*.

COCAINE A CURE FOR SEASICKNESS.—Dr. Manassese, of St. Petersburg, gives an interesting account of the employment of cocaine muriaticum in seasickness (*Berl. klin. Wochenschrift*, August 31, 1885). He argued from its usefulness in the vomiting of pregnancy that it would likewise be of value in this hughar of ocean travel. He made a voyage himself in order to test the drug, and, finding among his fellow passengers a man and a woman who were especially prone to the malady, made the following observation: Upon embarking, he administered to each every two or three hours a teaspoonful of a solution containing two and a half grains of muriate of cocaine in five ounces of distilled water, with the addition of a sufficient quantity of rectified spirits of wine. In spite of very rough weather for a period of 48 hours, both individuals escaped sickness for the first time in their lives. He also treated successfully a six-year-old child after it had begun to be sick, and a girl 18 years of age, who had been sick for 24 hours before the cocaine was given. Her case being severe, she was given a double dose every half hour, and the result is described as being "truly magical." She remained well during the rest of the voyage. Similar results followed in three milder cases. The writer thinks it justifiable to infer that in this drug we have a certain and harmless remedy against seasickness.

TO PREVENT BLEEDING AT THE NOSE.—The best remedy for bleeding at the nose, as given by Dr. Gleason in one of his lectures, is in the vigorous motion of the jaws as if in the act of chewing. In the case of a child, a wad of paper should be placed in its mouth, and the child should be instructed to chew it hard. It is the motion of the jaws that stops the flow of blood. This remedy is so very simple that many will feel inclined to laugh at it, but it has never been known to fail in a single instance, even in very severe cases.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

COAL NEAR LANCHANA PLANA.—Amador Ledger, Dec. 5: A sample of coal met with in the Stockton coal mine, 2½ miles northwest of Lanchana Plana, was left at the Ledger office on Saturday. It appears to be of a much better quality than that obtained from the mines in Lone valley. The mine is owned by a Stockton company, who located 80 acres of ground for mining purposes. They have done considerable work in developing the property. A shaft has been sunk to a depth of 100 feet, and in the drift run in a northeast direction a vein of coal six feet in thickness has been encountered. A large quantity of coal has been taken out, but none has been shipped as yet, although shipments are expected to be in order at an early date. Three men are working at present, and it is confidently expected that coal mining will become in the course of time a very important industry in that section.

GOVER.—This mine is now employing 30 men. The 20-stamp mill is kept running steadily; the ore is not of high grade, but there is plenty of it, and it pays something over expenses. About 10 men are kept on prospecting work, always a wise course in any mine, no matter how large and apparently inexhaustible the ore-body may be which is being operated upon.

MOORE.—All the indications at this mine are favorable. The work of sinking is in progress, the depth reached being somewhat over 250 feet. A ledge over four feet in width, and of paying quartz, has been discovered. The ore is not considered of high grade; but it is live quartz, that judging from appearance will yield at least from \$7 to \$8 per ton. Some ore of a much higher grade was taken out on Wednesday last. Assays of the quartz have given as high as over \$100 per ton; and the prospects by hand mortar would indicate an average of \$15 per ton. The sulphurets are also said to be of high grade, exceeding \$200 per ton. The present sinking contract will give the shaft a depth of over 300 feet. Sinking will no doubt be continued beyond that depth, although probably a new level will be opened, and preparations made to get the mill running. It is a noteworthy fact that the ore body appears to increase both in size and richness as depth is attained. Parties interested in this mine are very sanguine that it will develop into a big and permanent mine, and every day's developments seem to warrant their anticipations.

MISCELLANEOUS.—It is reported that negotiations are in progress for the sale of a controlling interest of the North California mine, near Drytown, to San Francisco capitalists, who are ready to buy stock at \$1 per share; there are \$15,000 shares in the company. A majority of the stock has already been deposited in Wells Fargo's office in Sutter Creek in acceptance of the proposition of the San Francisco parties; they have until April next to complete the purchase. The 5-stamp mill of the Lighthouse mine was started this week, with flattering prospects. The five-stamp mill which has been moved on to the St. Louis mine, near Pine Grove, was put in motion this week. The new hoisting machinery at the Kennedy is being put into position as fast as possible. The baling bucket, round wire cable, and new sheaves for the same are on the way from San Francisco. It is expected that everything will be in readiness to commence taking out water in two weeks.

Inyo.

WHITE HILL.—Inyo Independent: Twenty-five tons of ore from the White Hill mine were shipped this morning. Mr. Thomas Kehoe, one of the owners of the mine, will please accept thanks for several fine specimens. One of these specimens is a double cube of pure galena, about three inches by one and a half inches. The others are beautiful specimens of chloride of silver and sulphure of silver. The White Hill mine continues to be a good producer of fine ore.

PIUTE.—Last Wednesday ten tons of ore were taken down from the Piute mine to the Maxim mill to be worked. The Piute is twelve miles above Bishop station. There is said to be two hundred tons of ore on the dump that was taken out some time ago. If this sample is found to pay the whole amount will be shipped down and worked at the mill.

CHRYSOPLIS.—Mike Lasky and John Anton are doing assessment work at Chrysopolis. Since starting in this time the mine looks so promising that they think of working right along. A nice vein of gold ore has been struck at a depth of eighty feet; it is three feet wide and prospects well.

BROWN MONSTER MINE.—Bastian & Co. have about thirty tons of ore on the dump, and the pack train will commence packing ore on Monday. The first-class ore will be shipped to Selby & Co., while the balance will perhaps be sent to our local reduction works, when they get ready to run.

Mariposa.

PILING IT UP.—Mariposa Gazette, Dec. 5: Captain Diltz was in town yesterday, who says that the water from the recent rain has about all run down, hence his reservoirs and ditches are idle at present for the want of water. In the mean time he is wheeling out from his mine a large amount of vein matter, and piling it for milling and washing. The vein looks well and grows wider as it goes down. The strata and vein matter which carries the gold is some 30 or 40 feet wide and looks very promising. Should the rain-fall start up again, Captain Diltz will uncover a large amount of vein besides washing away considerable dirt.

Nevada.

BADGER HILL MINING COMPANY.—Grass Valley Union, Dec. 6: A meeting of the stockholders of the Badger Hill Gold Mining Company was held on Saturday evening to take into consideration an increase of the capital stock of the company and determine as to the resumption of work upon the mine, which has been standing idle for some years. There were several non-resident stockholders absent, but those present were in favor of increasing the shares from 500 to 50,000 so as to provide a working capital. The expression of the meeting was also in favor of resuming work, and it is understood that the

mine will be started as soon as the necessary arrangements can be made, within the next few months.

Placer.

GOOD CLEANUPS.—Herald, Dec. 2: A crushing of about 15 tons taken from a north extension of the Boulder mine by Fred. and Jacob Kaiser and J. B. Brown yielded a little over \$10 to the ton. They are down about 80 feet and have a two-foot ledge. On a cross lead in the same locality Louis and Charles Kaiser have just taken out a crushing which yielded a little over \$26 to the ton. Chas. Williams and Henry Johnson, on Rocky Ridge, finished a crushing in Pelster's mill the other day that went about an ounce to the ton. From an extension of the old St. Lawrence the Kittler boys have recently taken out a crushing of ore, which paid very satisfactorily.

A GOOD CRUSHING.—Sixteen tons of ore recently taken out of the old St. Lawrence mine, near Ophir, by Sam. Kaiser, Peeler Lozano and John Romero Jr., yielded something over \$50 per ton. The boys are now putting up a whim and making other necessary improvements, and in a few days will be ready to commence operations again in good earnest. The St. Lawrence belongs to Mr. Chas. Reed, of Ophir, and is no doubt a good property. This mine, some 10 or 12 years ago, was owned and run on a high-pressure scale by a San Francisco corporation, but from some cause was closed down, leaving the impression that the lead was worthless. It is, therefore, an illustration of what is frequently the case in California, wherein old and abandoned claims under practical and more economical management are being made to pay.

Plumas.

FOREST KING.—Greenville Bulletin, Dec. 2: Ten stamps of the Kettle mill have been put in order, and as soon as the condition of the road will admit hauling of ore from the Forest King will be resumed and the mill started. This mill is quite conveniently situated with reference to the mine, and will probably be kept running all winter.

INDIAN VALLEY MINE.—After a stoppage of about a week, occasioned by the inability to get suitable miners, the mill at the mine resumed crushing yesterday (Tuesday) morning. Mr. Cornell is expected from the city soon, where he has made arrangements to obtain all the skilled labor that the mine will hereafter require. Once more under way this mine will undoubtedly continue to run steadily throughout the season. The late storm assures a steady supply of water power from the Round Valley reservoir, and the developments in the mine continue to be of the same splendid character as recently noted. The owners have not feared to make a generous investment before expecting returns, and are now meeting with a deserved reward, while the community is correspondingly benefited.

GIBSONVILLE.—Cor. Plumas National, Dec. 3: Since 1850 there has been a prosperous mining town, and it would seem to have a good future before it. The Union, the North American, the Bunker Hill, and three other mines that are to be opened up in this immediate vicinity, will make Gibsonville what it was in early days. The Union mine, now owned by Messrs. Cahrs and Judd, is being worked by a strong force of men, and is proving as rich as it is inexhaustible.

Shasta.

PLACERS.—Shasta Co., Democrat, Dec. 2: The placer miners of Buckeye district are putting in their besticks, rain or shine. Reid & Co.'s mill on Star gulch was shut down yesterday to permit a cleanup, after having run through about 90 tons of ore. Billychoop from all accounts is a promising mineral field and is now receiving no little attention at the hands of mining men. Stamp mills in the near future will add stability to its progress and lend influence to its speedy development. Reilly, Mathews & Co. who purchased Conant's Squaw creek mines resumed work on the road to the camp from the railroad last Monday, and we are told it will be finished in a few days, when a ten-stamp quartz mill will be hauled over the road. The route now being utilized is but temporary. Some time in the future it will be improved.

San Bernardino.

CALICO MINES.—Print, Dec. 5: All the principal mines in Calico district are looking well, employing the usual number of men and turning out the usual amount of bullion. The Silver King one of the principal pillars that support the town of Calico, has attained a depth of over 600 feet and is turning out enough good ore to keep the 15-stamp mill almost in constant operation. There is every reason to believe that the mine will reach a great depth and continue to pay dividends to its owners for many years to come. The developments made in the Garfield are frequently wonderful, immense chambers being excavated that yield hundreds of tons of high-grade ore. The mine keeps Barber's 10-stamp mill in constant operation, and has reached a depth of over 500 feet and still shows no signs of exhaustion. The Silver Odessa is now a well developed mine and has an appearance of being a permanent one. It keeps the company's 10-stamp mill at Hawley constantly running at full capacity on ore that yields large dividends. The Bismarck is employing a small force of men taking out several tons of rich rock daily from the surface, and from points probably not deeper than 30 feet. The extent of this mine will be more fully determined when a greater depth is attained, and developments are prosecuted more extensively. It has been a paying property from the start. The Occidental has a large force at work principally taking out high-grade ore, not much dead-work and prospecting being being done. It is being worked with considerable profit, and it will be a long time before even the ore in sight is exhausted, and that it will reach considerable depth is guaranteed by its proximity to the Garfield. The Sue is still being worked at a profit, though small, and much smaller than when the present company first took hold of it. The ore appears to lie in rich pockets, but not in large quantities. The ore is hauled to the Waterman Mill. The Waterloo is progressing in good shape, considerable ore being extracted of fair grade. The mine improves as work advances and there is every reason to believe that it will develop into a good paying property. The Plutarch is looking better than ever and shows up plenty of low-grade ore that would pay a rich company to handle, and yields enough high-grade to make it an advantage for the owners to continue developments. There are a number of mines that are being worked to advantage in a small way, some of which are liable to develop into fine properties. There are not so many chlorides to work in the camp as there were this time last

year, some of the mine owners believing that digging up mines in any shape in search of rich ore injures them and lessens the chances of selling. The Last Chance mine which has been showing up well for some time during John Benefiel's lease was sold the other day to Messrs. Gillespy & Childs.

Trinity.

DEADWOOD.—Cor. Trinity Journal, Dec. 5: The richest ore we have seen for some time is that recently extracted from the new strike in the Brown Bear mine. The new ledge has every indication of permanence and value, and we hope that it will prove thus as it is in the hands of good and enterprising men who do a good share of benefit to the county. Westlake & Cosgrove have made a cleanup of the most satisfactory results, \$60 per ton. Everyone, as it appears, condemned the ore, saying it would not mill over \$10 per ton, and Westlake says he has taken many a drink the past week over bets made previously on the same. Wm. Blagrave has made several cleanups, the ore working over \$100 per ton. Rich rock is still being extracted and a good mine is being developed. Gibson & Leavitt, upon their small vein, have good ore. A shaft sunk about 50 feet proves the vein as good as ever. George Chenoweth will soon commence operations on the old Black Bear mine owned by Mr. John Gibson. George is a good enterprising miner and will succeed where others will fail. Minear & Co. are doing active work. Their lower tunnel will soon be into the ledge. Jud and Walter Van Matre have so far a bonanza.

EAST FORK.—Cor. Trinity Journal, Dec. 5: The North Star Co.'s five-stamp mill has been running four or five days and is a complete success in every respect. The boys are very busy putting their roads in order from the mine to the mill. Day & Moor's arastra is running day and night on very high grade ore, and the mine is looking remarkably well. Charles Hippler & Sons are busy repairing their ditch which was damaged by the recent storms. They will have their arastra running in about ten days. Abbott, Giffith & Sheehy are excavating for an arastra at the mouth of Barney gulch, having just finished their ditch, and expect to have the arastra completed by the 1st of January. They will work ore from their mine on Rich gulch, the prospects being very promising. The latest discovery is that made by Gustin & Bailey and named the Thanksgiving mine. Present developments show it to be one of the richest ever found in the county. When first discovered the rock prospected about \$10 per ton and has since kept increasing both in richness and extent. They have a tunnel on the ledge a distance of 40 feet, in the face of which the ledge is full 30 inches and will go from \$75 to \$150 per ton. There is water sufficient to run a 10-stamp mill by water-power all the year round, crossing the claim, and an inexhaustible supply of timber for mining purposes.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Enterprise, Dec. 5: In this mine, during the past week, the main lateral drift north on the 3100 level was advanced ten feet since last week's report. On Wednesday last work was discontinued at this point and two crosscuts started east at a point seventy feet north of the deep waste station. The east crosscut is now in fifty feet and the west crosscut the same distance. Material in the face of north drift, vein matter, looking splendidly. On the 3000 level a small quantity of ore is being extracted from the ore body in which the deep waste has been sunk below that station or level. It is proposed to go on and stope out this ore as high as to a connection with the 2900 level.

THE KEYES MINE.—There is really a good mine in Six-mile canyon, which has had to lie idle for several months on account of litigation. Recently the long continued suit between Dr. D. A. Hiller, of San Francisco and P. J. Keyes has been amicably settled, and work is to be started up again in the mine about January 1st. The shaft is nearly 300 feet deep, well timbered throughout. The ore is in a series of small veins or portions of a main vein, and the ore is of the rich black sulphuret order. It is estimated that there is nearly \$40,000 worth of ore in sight, which can be extracted at little expense. There are good steam hoisting works at the top of the shaft, with requisite buildings, etc.

CHOLLAR.—The main south lateral drift on the 3100 level is being pushed ahead as usual, being now in 560 feet south from the Combination west drift. The material encountered is dry, hard, black dyke lying next to the diorite of Mount Davidson, and to the westward of the main ore vein. The rock continues hard, but good daily progress is made. No crosscutting is talked about as yet, neither is there any talk at present of sinking the Combination shaft deeper. The hydraulic pump continues to work to perfection.

CON. CALIFORNIA AND VIRGINIA.—The old 1750 level continues its regular yield of 125 tons per day, supplying the Morgan mill. Average assays, \$15 per ton. From the Jones contract section, above the 1500 level, about the same daily amount is being extracted, which is shipped to the Eureka mill. Average assays about \$30 per ton. The drift northwest on the 1650 level is being pushed ahead steadily towards the old ore stopes.

YELLOW JACKET.—Daily yield, 175 tons from the old upper workings above the 1300 level. The main lateral drift on the 1700 level, from the Crown Point through the Kentuck, continues to make good progress northward toward the ore body expected to be found in that part of the mine.

CROWN POINT.—The usual supply of low grade ore to keep the mills running continues to be extracted from this and the Belcher mine. Explorations continue on the 1700 and 1750 levels, where some good ore is found, but not of very high grade or in great quantity.

OPHIR.—The main lateral drift south from the west crosscut on the 400 level is now in 290 feet, with a good continuance of low grade ore in its face. The west crosscut from this lateral drift is in 122 feet. Face in good vein material, carrying occasional streaks of ore.

KENTUCK.—Old regularity goes steadily ahead, as usual, yielding sufficient ore from the upper workings, above the 1300 level to keep the Rock Point and Douglas mills steadily running.

MEXICAN.—On the 500 level, the north lateral

drift from the east crosscut is in 165 feet, and the south lateral drift opposite to it, 166 feet. Both are running in very favorable vein matter.

GOULD AND CURRY.—On the 1000 level, west crosscut No. 2, which is in 170 feet south of the north line is in 204 feet. Material, dry vein porphyry, with streaks of quartz and clay.

UNION CONSOLIDATED.—On the 500 level, the crosscut east, 100 feet south of the Sierra Nevada line, is in 317 feet, and making good progress in very favorable vein material.

ALTA.—The explorations on the 700 level near the upraise from the 950 level, show good bunches and streaks of pretty fair ore, but no bonanza as yet.

BEST AND BELCHER.—On the 1000 level, west crosscut No. 3 is in 234 feet, and progressing well in good vein material, decomposed quartz, porphyry and clay seams.

Columbus District.

HOLMES.—True Fissure, Dec. 5: We made, during the past week, a fine development in a raise above the intermediate, that we call the Crummer raise. After we broke into the body of ore we drifted on it, and now it is 5½ feet wide for fifteen feet in length, and looks exceedingly well. We think this is the continuation of the McClane bonanza. From the Cross development we are taking some good ore. At point 18 we are still driving the drift. The ground is a little more favorable, and we are making better progress. The Creer drift looks better than at last report. The ledge is 12 feet wide and there are two streaks of waste in it that are equal to three feet in width. The balance will go to the mill as it comes out. This ore body is on the same ledge as the hot stope, and some of the ore is very rich. The car samples from here will average \$75. This is a very important prospect, being further north than any work done in the western portion of the mine.

POTOSI.—The lessees are taking out three tons of good ore from the Monk and Jolly workings every week, and four tons per week from the Potosi No. 1. All the stopes are looking well. As soon as they can get the sacks they will ship two carloads to Selby & Co. The boys were very much pleased with their last returns, and expect to do even better next time.

RUBY.—Mt. Messenger, Dec. 5: The last Ruby cleanup amounted to 123 ounces, and a dividend of \$6000 has been declared. About 40 men are employed. The Extension Co. cleaned up last Sunday 322½ ounces. The directors declared their fifth dividend (the first from the extension ground) Nov. 30th, payable Dec. 1st, of ten cents a share, aggregating \$6000, and, hereafter, there will be similar regular monthly dividends.

Jungo District.

PROVING RICH.—Silver State, Dec. 4: The Lottery mine in Jungo district, which is situated about 55 miles west of town, is proving to be very rich. It was located by W. C. Owens and Richard Nagle, and it is prospected to a depth of 23 feet from the surface. At that depth the vein is about six feet wide, and there are streaks of ore from two to six inches wide through it that assay several hundred dollars to the ton. A chunk of the ore, which would probably weigh four pounds, was exhibited at the courthouse yesterday, and good judges pronounced it free milling. It is principally chloride, and resembles the rich ores of the Ohio mine at Rebel Creek.

Hawthorne District.

THE YELLOW JACKET.—Walker Lake Bulletin, Dec. 9: The Yellow Jacket arastras are now at work on ore from the mine, and while the result will not upset the bullion market, the profit will be a very comfortable income to the owners. The mine, which for some time has been known to be one of the best and surest properties in this section, has latterly shown much improvement, and if it continues as it now is, it will not long be considered a little mine. This ledge is situated in that part of the country where all experts were satisfied nothing could be found, but, as the owners have the gold, they are willing to allow others to keep the theories.

SALE.—On Saturday, John Hendry sold all his interests in Hawthorne and Moss mining districts, to a company composed of Hawthorne people. This sale includes half of the celebrated Red Bank, in Hawthorne district, and half of the mines at Kinkead, which yield very rich gold rock.

Hiko District.

HIGH GRADE ORE.—Cor. Eureka Sentinel, Dec. 3: In a former letter to the Sentinel on the mineral resources of this district, I inadvertently made mention of the collapse of the Hiko Mining Company, attributing it to the inexperience of the managers. At the time I wrote the letter it looked very much as if mismanagement was the cause of the failure, but as the principal manager, Eugene Howell, has since shown himself, by actual results, to be an entirely competent mining man, I hasten to give him all the credit of his late achievements. Those achievements consist of unearthing large bodies of high grade ore in two of his mines and the working of the same up to 87 per cent of their assay value, and if he did not have to surrender the mill, which belonged to Mr. Burton, he would in a few months have cancelled the entire indebtedness of his company. As it is he has paid the greater portion of the outstanding bills, and hopes before long to have the wherewith to build a substantial mill at the mines. It is no exaggeration to say that if the mines of Hiko were in Colorado or Utah, or even in some accessible locality in this State, they would be worked extensively, for the country for miles around is one solid mass of mineral-bearing rock, scattered promiscuously and volcanically in all directions. This rock, or rather ledge croppings, will assay all the way from \$5 to \$30 per ton, sample pieces going away up in the hundreds.

Pennsylvania District.

COMING TO THE FRONT.—Cor. Eureka Sentinel, Dec. 3: Pennsylvania district, which is some 26 miles from Bullioville, is coming to the front, Mr. Barton being busily engaged in erecting a 10-stamp mill on the well-known Klingensmith mine. This property, although known to be a first-class one, has lain idle for years. The ledge is 16 inches wide, of free milling quartzite, five tons of which were lately worked at Mr. McFadden's mill in Pioche and yielded \$45 dollars per ton in silver and \$10 in gold. A shaft has been sunk on the property to a depth of 160 feet, where the ledge has been found stronger than on the surface. Experts who have visited the mine from time to time have pronounced it as resem-

bling the true fissure vein of the Comstock more than any claim they have ever seen. As Mr. Burton has some 3000 tons of ore on his dump, together with an abundance of wood and water close by, there is a snug little fortune awaiting him in the Klengen-smith.

Pioche District.

MAY BE BETTER.—Cor. *Eureka Sentinel*, Dec. 3: It need not surprise the readers if the town of Pioche should take on new life before many months, as parties who mean business are negotiating for the purchase of the famous Raymond & Fly and Meadow valley mines. I am aware that this statement, in view of the many similar ones that have been published from time to time, will be looked upon with suspicion by the general reader, but in this case I know whereof I write.

Spruce Mount District.

FURNACE STARTED.—Pioche *Record*, Nov. 28: A letter received from there, states that the furnace was started up, and that it worked like a charm. The yield is from 75 to 80 bars per day. This is the third time the furnace at Spruce Mount has been started up, but until the present time could never be made run successfully, as then stated, owing to the rebellious character of the ores of the district, but after R. C. Walsh, who went from Bristol to that place, did some experimenting with the ore and furnace, he has succeeded in knocking all the rebelliousness out of the ore, and the silver and lead flow through the furnace as smoothly as could be desired. Owing to his success as a skillful furnaceman Mr. Walsh has been appointed Superintendent of the Spring Mount S. M. Co. There are 1500 tons of ore on hand at the furnace, and a run of at least 75 days will be made. As the silver bars are shipped away, mining news from Spruce Mount will hereafter be interesting.

Tuscarora District.

ARGENTA.—*Times-Review*, Dec. 4: West drift on the 400 has been advanced 12 feet during the week.

NORTH BELL ISLE.—No change to note. Good progress has been made with the work on the 150-foot level.

BELLE ISLE.—North drift from crosscut east, 450-foot level, advanced 12 feet the past week; total length, 94 feet.

GRAND PRIZE.—North drift on the 300 level has been extended 13 feet during the week, and upraise above same level up 74 feet.

NAVAJO.—No. 1, crosscut west, 350-foot level, advanced six feet. Crosscut No. 2, 250-foot level, advanced five feet. West crosscut from the east lateral, same level, advanced six feet. South drift, east vein, same level, extended two feet. South drift, east vein, 150-foot level, advanced 15 feet. North drift, west vein No. 2, same level, advanced 16 feet.

Victoria District

GOLD LEDGE.—Walker Lake *Bulletin*, Dec. 9: The gold ledges discovered in Victoria district are reported to be very rich, and it is said that Hawthorne district will soon find its equal. Everybody is willing.

ARIZONA.

MOHAVE COUNTY.—*Miner*, Dec. 6: A lot of ore from the C. O. D. mine is expected at the concentrator in a day or two. This mine is turning out lots of good ore, and the whip is kept busy in hoisting it out. Mr. Ryan, the superintendent of Raymond's Concentrating Works, having placed the concentrating machinery in thorough working order, has placed W. R. Jones in charge of it, and is now turning his attention to the leaching process, which he intends to use in connection with the concentrator. He has already commenced work on the necessary vats. Ed. Burke will start up work on the Cupel shaft in a few days. This claim is owned by J. W. Yoacham, of this town, and is one of the best looking prospects on Stockton hill. Work on the I. X. L. mine has been suspended until after January 1st, the owners having to put in the balance of the year on assessment work on other claims. The Signal ro-stamp mill is expected to start up about the first of the year. Several parties are doing assessment work on their claims near town, and shots are going off in every direction. Beecher & Co. shipped a 400 bar of gold bullion yesterday for Eugene Fourtillot, who has just had a batch of ore from the Vanderbilt mine worked at the concentrator. One of our miners had as many as fifty assays made last month, and yet, in spite of all his care, discovered that he had been throwing 682 ounces over the dump. Fortunately, it can be easily sorted out, but this incident shows that one cannot be too careful.

COLORADO.

ELK MOUNTAIN.—*Pilot*, Dec. 3: Garret Fitzgerald shipped a carload of ore this week to the Moffat smelter from the Daisy lode in Redwell basin. The Pine Tree lode in Redwell basin, is being worked by James Affly and John Jones. At present they are running a crosscut tunnel to cut the vein of the Pine Tree lode, also the Daisy vein owned by Fitzgerald *et al.* Frank Winters has leased and bonded the Volunteer mine at Ohio city, and will begin work on it immediately and continue it all winter. Mat O'Loughlin has recently come back from a trip to some placer property situated about 8 miles west of Gunnison, and owned by himself and Capt. John Tetard. He purchased some additional interests while there, and did considerable work, building a tail ditch, etc. He has very great faith in the future greatness of their placer interests there.

CRYSTAL CITY.—A drift has been started from the Black Queen shaft at a depth of 110 feet, and they are taking out some fine ore, keeping three shifts at work. The Lost Horse is looking good and giving encouragement to the boys. Several sales are about to be made around this section which will be of great benefit to our camp.

IRWIN.—The Hopewell mine in Irwin, that is being worked under a lease by Tom Hodgson, Edgar Johnson and Simon Kautler, is now producing some mineral, we believe. The work is done in a shaft of the vein, and about 200 feet down the creek from the old shaft. The vein is right in the bed of a creek and no little trouble is experienced from water. The Ruby Chief has a new ore house built and everything under cover for winter work. The National mill is still running on the tailings that have been left at the mill for two or three years, and so

far as we can learn with good success. Mr. Metzler expects to run the Rose-Reed concentrator this winter. Mr. Nichols, who has had charge of putting the mill in order, feels confident of success.

WINNING CARD.—Georgetown *Courier*, Dec. 3: The last carload of ore shipped from this property was estimated to be worth nearly \$12,000.

EQUATOR.—This mine is producing quantities of good ore. A mill-run was made from the property this week.

BROWN.—The mine has been leased to Harry Lampshire, who is putting in air pipes and otherwise getting the property in working condition.

BELL CITY.—This lode on Covode mountain is now being worked by H. J. Blatter, and at the bottom of the 25-foot shaft, shows a nice streak of ore, which runs well in gold.

STEVENS.—Drifting is going forward each way from the Matt Harris tunnel, showing ore in each place. The stopes on the seventh and ninth levels are yielding well. The ore carries an average of 45 ounces in silver and 64 per cent lead.

CANIER.—The main shaft on this Empire property is being sunk at the rate of 20 feet per month, and exhibits excellent indications for the future. The drift is being driven and a crosscut of 32 feet run toward the south wall without striking it.

INDEPENDENCE.—But few men are at present operating on this mine. C. T. Gleason is the main lessee. He is stopping on about two inches of mineral above the No. 3 level, where he has extracted ore that returned 326 ounces. His last shipment of 2600 pounds returned him 189 ounces silver to the ton in one class.

JOHNSON.—Eight men are now at work on the property, situated in Argentine district. Carlson & Co. are stopping above level No. 3, upon a nice streak of mineral. Johnson & Peterson are sinking a winze from No. 4 to No. 5 level and begun drifting on from four to five inches of ore. The ore streaks in the mine range from one to six inches in width and yield from 70 to 360 ounces silver to the ton.

IDAHO.

SMELTER CLOSED DOWN.—Idaho *Messenger*, Dec. 1: The Clayton smelter closed down for the winter on the 25th of November, after the most successful summer's run it has ever made, leaving everything in the best possible condition—the ore houses empty, the coal bins empty, and the machinery in fine shape for another successful year's run. The output this year, although we do not know the exact figures, has been very large, and aggregates about 700 tons of bullion, matte and high grade ore, of the average value of not far from 500 ounces per ton, or a total product of \$350,000. A. J. Crook departed at once on the closing of the smelter for the East, and will probably not return before spring. The subordinate management, also, and most all of the laborers of the camp left at once, when the smelter stopped, and the town of Clayton, as well as the smelter, has, in the strict sense of the term, "closed down for the winter."

WOOD RIVER OUTLOOK.—*Times*, Dec. 5: Notwithstanding the general opinion to the contrary, business is better here now than ever before. There is five times as much money in circulation here now as a year ago, the dealers in general merchandise are busy from morning until night, and the volume transacted is double what it was a year ago. True, the profits are not as great; but on the other hand there is much less credit sought or given, and losses are smaller. The merchants are "solid" to a man. Our main dependence is upon our mines. They, thank goodness! are improving continually and their yield is increasing. From every section, district and ravine, almost, the news of improvement comes. The Lava Creek country is already demanding reduction works, and at least two mills will be erected there in the spring. The Little Wood River country contributes two or three groups of new mines, and even now estimates and plans are being prepared for a 60-ton concentrating works for Colonel Havens and ex-Marshall Shaughnessy. Resurrection district shows good mines, and Hon. John Hailey is making it his business to study out the best process for reducing their ores, with the view of building reduction works on Silver Creek in the spring. The Lee's Gulch and Broadford district continues to open up satisfactorily, one of the mines there—the Queen of the Hills—showing fully as well as any mine in Idaho. Deer Creek, as everybody knows, has recently shown up new deposits that promise exceedingly well, and if the unfortunate Montana-Snowfly-Taylor-Motherwell-etc. controversy is ever settled the yield of the mines along this tributary will be quadrupled. At Bullion the Bay State, King of the Hills, Mormon Girl and other groups are being put in shape for a heavy yield, while the Idahoan has enough in sight to insure a daily yield of \$1500 for an indefinite period. The upper country is looking better than ever, notwithstanding one of its foremost groups has ceased to yield. But Crook gulch is still the main artery, the region holding forth the most promise. In the Climax, within a mile of the Hailey bridge, there is a bonanza of unknown extent, but for which \$100,000 is said to have been offered; and Colonel Wall's trip out now is stated to have something to do with this proposition. Across the gulch, evidently on the same lode, the Fearnought continues to yield small lots of shipping and a large quantity of concentrating ore. Up above the springs the Idaho Democrat shows a new body of rich ore. But the quarter which gives us the most hope is the gold belt, as the formation there justifies the wildest anticipations. As repeatedly stated in these columns, there are several wide parallel veins of gold-bearing ore that, if properly opened, can give steady employment to thousands of miners, millmen, woodchoppers, teamsters, mechanics, etc., and be made to yield hundreds of millions of dollars. One 20-stamp mill is already at work there, and another—a Wiswell, with a capacity equal to 15 or 20 stamps—will doubtless be before Christmas. With two mills in operation, and conducted by thoroughly competent mine and millmen, the district will soon receive that crucial test which can alone give investors that confidence that will cause them to secure property in the district, and cause it to "boom." As above stated, our mines are our main reliance. With them we will prosper anyway, as even though Congress should be hostile to silver and lead it cannot legislate our gold out of value. There is no discount on gold, and cannot be. The outlook for this region is therefore better than ever before.

MONTANA.

PLACER STRIKE.—Butte *Inter-Mountain*, Dec. 2: This morning Charles S. Warren received a dispatch by telephone from Thomas Wallace, of Missoula, requesting him to forward the names of five men in Butte, who, with others, would organize a company for the purpose of developing placer claims in the Big Hole country. Half an hour later the gentleman wired Missoula the following names: G. W. Stapleton, S. A. Estes, Lee Mantle, G. W. Irwin, Charles S. Warren. The company will be at once organized and active operations commenced. The intelligence received from the new gold field, for such it may now be properly called, is almost startling, and many are of the opinion that a second Alder gulch has been discovered. Saturday last, Mr. George Orr and Thomas Hughes took out of their claim with a common rocker, \$120 in gold. Monday, Billy Edwards cleaned up after a week's operations, and sold to the Missoula National bank, gold dust to the amount of six hundred dollars. Such statements as these have in them the ring of early days, when the virgin gold fields of Montana attracted an eager throng from every quarter of the globe, and these facts are vouched for by unquestionable authority. It is a striking coincidence that the two men, Orr and Thomas, who have struck this placer bonanza, belong to the Fairweather party that discovered the rich treasures of Alder gulch. The golden harvest they gathered twenty years ago was scattered with a lavish hand, and they were obliged to return to lives of privation and toil. But undaunted by frowns of fortune, they have steadily persevered in prospecting expeditions until their labors have been again crowned with success. The new mines are located in Monument district, named after a granite shaft erected to the memory of the brave men who fell in the bloody battle of the Big Hole. The diggings are at and in the vicinity of the battlefield on the north fork of the Big Hole river. The nearest route by which to reach the district from Butte is by Mill Creek, on the trail leading north of French gulch to the river. Thence it is only necessary to follow up the stream. The distance from this city is about one hundred miles.

NEW MEXICO.

HIGH GRADE ORE.—Silver City *Enterprise*: The Cow Springs district is producing some very high grade ore. The Novelty mine at Gold gulch, shipped 20 sacks of first-class ore this week. Development on the Silver Bell mine in Chloride flat has shown up some rich mineral. The property is owned by Owens & Lloyd who consider it a most promising prospect. Seven bricks valued at \$10,000 were shipped by the Mimbres company this week. During the first 30 days run of the mill 27 bricks, worth \$34,000 were shipped by Mr. Pehey. No other mining camp in the country can make a better showing. The Young Man mine, at Gold gulch which has been worked for the past month is looking and producing well. A great deal has been said recently of the Slayback and Free milling claims in the Mogollons. The vein averages from 20 to 25 feet in width, and the assays average from one to three ounces in gold and from 18 to 20 ounces in silver. These claims are considered to be the best prospects in the Mogollons. The Providencia, which for years was the bonanza property of Grant county is again producing mineral that will average over \$500 in considerable quantities.

BLACK HAWK NOTES.—A good strike has been made in the Tom Jasper mine. The ledge shows 18 inches of native and horn silver, and it is regarded as one of the best ever found in the camp. The Rose is producing the finest ore in the history of the mine from a depth of 130 feet. This is a new and rich strike. The Black Hawk will start up in a few days as the necessary machinery arrived on Wednesday from Denver. Lowthian and Eckles are developing their property at Mineral Spring and are showing some fine ore.

OREGON.

DEVELOPMENTS.—Grant's Pass *Courier*, Dec. 4: Some very good developments are now being made on Foot's creek, seven miles above Grant's Pass, among them a prospect owned by Mr. Cliff Smith, of this place. Mr. Snelson, on Grave creek, near the mouth of Wolf creek has a good paying claim, for the amount of work done. He commenced on this property last fall, and developments thus far are very encouraging. Charles and Joseph Neill, are working a claim on the Jones creek ditch below Mr. Todd, which they purchased from him. They are well fitted up for ground-sluicing this winter, and as the formation of the ground and character of the gold is about the same as above, we doubt not they will take out considerable money this winter. From a gentleman who came up from down Rogue river a few days since, we learn that all the placers are in full blast in that vicinity. Mr. Jack Layton, one of the energetic men interested in mining in Josephine county, has a claim he has been working for years on Farris gulch, a tributary of Williams creek. The gold taken from these diggings is coarse, but of a very fine quality. Walter Simmons on Rogue river has one of the best fitted up claims in the county for sluicing. This mine is supplied with an abundance of water, and the manager will this season clean up a large area of ground, some of which would have been worked last year, but for the scarcity of water. The gold found in these diggings is of a very fine quality, and it is considered one of the best in this county. All the mines in the vicinity of Waldo are now in full running order. On Saturday last it was our pleasure to visit the mine of Mr. Geo. L. Todd three miles north of Grant's Pass. This mine was formerly the property of Campbell and Todd, before Mr. Campbell's retirement. Mr. Todd assumed the management and has been successfully working it since. The mine usually runs seven months in the year, but last season not being a good one the bedrock was not cleaned. Mr. Todd is now ground-sluicing, and the formation being of a loamy nature is easily got away with. There are now about ten miles of ditches on these diggings taken out of Jones' creek, and three miles out of Bloody Run. Generally considered, this is a handsome property.

NOTES.—Bedrock *Democrat*, Dec. 5: Charley Robinson has hauled all the heavy machinery from the depot to the Virtue mine. Wednesday George Boreman hauled a two-horse load of powder, Hercules No. 1, to the Virtue mine. The rich strike in the placer digging on Connor creek is well deserved.

The parties who made the strike have been engaged for two or three years past in running a bedrock flume, and until last week realized but little for their work. Their perseverance is deserving of success.

UTAH.

STAR AND LINCOLN.—Cor. Salt Lake *Tribune*, Dec. 3: The Harrington and Hickory mine is looking fine and a big dump of ore attests the truth of the matter. Considerable work is now going on throughout the entire district. A force of miners have been put on the Wild Bill and Flora mines. Peter Martin and J. F. Brown have struck a rich body of ore in the Monarch mine, Eureka hill. J. H. Cook has found 200-ounce ore on the St. Mary's, Monitor, Mammoth, Burning Moscow, Creedmoor, and many other claims with good results. The shutting down of the Campbell mill at Milford has not retarded the future outlook of the district, as it has been demonstrated that nine-tenths of the ores are concentrating and can be concentrated for \$2 per ton, and if Mr. Campbell does not work custom ores somebody else will, as a mill to concentrate ores alone can be constructed nearer Star than Milford for \$8000 with a capacity of 20 tons per day, and a well can be sunk that won't cave in. In the foothills of Star and in Lincoln districts there are silicious ores that will average 12 per cent lead, 20 ounces silver and from \$8 to \$20 in free gold that will pay to concentrate, but not to ship to Salt Lake and pay \$25 to \$30 per ton to smelt. Now here is a chance for some bright, enterprising man of means to erect a custom mill to concentrate the ores of Star and Lincoln, and do it before the resident miner dies with old age.

PARK NOTES.—*Record*, Dec. 5: The Ontario mill shipped for the week ending Nov. 30th, 90 bars of bullion, containing 63,351.37 fine ounces of silver, valued at \$59,686.50. The Morgan people have cut the apex of the great vein in their Maryetta shaft. The vein stuff is very similar to the Daly ore. We are informed that Charley Dolberg has sold his group of claims for sixty thousand dollars to Eastern parties. They adjoin the Morgan property on the southwest, and cover the apex of the Daly vein. Westerly, and adjoining the Dolberg group is situated the claims of Bogan & Co. They have run a tunnel south about two hundred feet, crosscutting the vein about two hundred feet below its apex; on its dip to the northwest, the vein is about two feet thick, somewhat broken, yet carrying high grade ore. Some two thousand feet westerly from the Bogan property, Hunter & Co. have run a tunnel southerly about six hundred feet, crosscutting the vein about five hundred feet from the mouth of the tunnel. The vein is large, but broken, and carries a high grade ore. The owners have been drifting westerly on vein. The vein, when crosscut, is about 400 feet below the apex. This property has a bright future. Doctor Reed is engaged in making a raise on his vein from the level of the lower tunnel to connect with his upper workings. The vein is about four feet between walls, and carries bunches and stringers of very high grade ore. When air connections are made he meditates drifting easterly. This property is undoubtedly located on the great Ontario belt. The doctor deserves success, having expended some thirty thousand dollars in developing this great property.

REVIEW.—Salt Lake *Tribune*, Dec. 4: The receipts of bullion in this city for the eleven months of the present year are shown in this table. It shows bullion receipts only, excluding all ores. Necessarily, also, it fails to include the product of a number of producers that make no current reports:

January	\$378,644.56
February	237,536.78
March	273,771.69
April	359,983.27
May	238,620.43
June	361,076.16
July	260,567.40
August	321,912.78
September	319,079.40
October	420,855.92
November	419,853.28
Total	\$3,765,902.67

Of course, the actual output was much in excess of this, though the above includes some bullion from Idaho and Montana. Yet the unreported product, together with the shipments of ore to smelters abroad, would largely overbalance our debts on outside bullion account. The receipts of the metals in this city for the week ending December 2d, inclusive, were—of bullion, \$65,669.78; ore, \$16,041.49; total, \$81,711.27. The previous week the receipts amounted in aggregate to \$153,784.17, of which \$127,734.99 was bullion and \$26,149.18 was ore. No Ontario output is reported for the week, but all is going well at the mine and mill. The Stormont sent up from the Silver Reef sandstones three bars of silver, \$3390. The product of the Hanauer smelter for the week was nine cars of bullion, \$29,470; of the Germania, four cars, \$7866.67. Ore receipts were \$2278.97 from Southern Utah, \$2700 from the Crescent, \$2520 from the Sampson, \$323.52 from the Toledo, Utah; \$4200 from the Queen of the Hills and \$4020 (15 tons) from the Bannock, Idaho.

CHRISTY.—Southern Utah *Times*, Dec. 3: A few weeks ago, a blue colored sandstone was encountered in the ledge in the upraise on the 500-foot level in the California, which is attracting considerable attention among our experts. The ore has not a sign or marker to distinguish it from common country rock, although it carries a good percentage of silver. There is probably a big body of it, as it runs across the bottom of the drift and is eight feet wide in the stopes. John Barbee shipped five tons of good grade ore from the old Bonanza mine on the White Reef to the Christy mill this week. Ottman & Miller and James Carroll made shipments from the Maggie to the Christy mill during the week. James McDonald also made a small shipment from the Tecumseh to the same mill. Al. Hartmann and Jack Pierce have struck a bonanza on the old Leeds ground. They have three feet of ore, four inches of which averages over 100 ounces. Their lease does not expire until January 1st, and they have over 20 tons of ore on the dump. There are more than 75 chloridizers at work in the camp and the number is constantly increasing. If capitalists knew one-half as much about the value of the sandstone silver deposits as the miners do, Silver Reef would be the best camp on the coast. As it is, the Reef is getting to the front in good shape.

TATUM & BOWEN,

25, 27, 29 and 31 MAIN STREET, SAN FRANCISCO.

91 and 93 FRONT ST., PORTLAND, OREGON

Manufacturers of

MINING MACHINERY, ENGINES, BOILERS, Etc.

We are manufacturing from Special Designs of the most experienced and successful Practical and Scientific Experts, Complete Plants for all descriptions of Mining Operations, as follows:

CONCENTRATING MACHINERY—Best and Cheapest, Cornish Rolls, all Steel Wearing Parts, Most Practical Styles of Two, Three and Four Compartment Double and Single Jigs, Sizing Screens, Patent Hydraulic Separators, Tables and Concentrators.

STAMP MILLS for Reduction of Gold and Silver Ores, whether free milling or base. Most useful and substantial styles of Single and Double Discharge Mortars, Wet or Dry Crushing.

STEEL SHOES AND DIES, Tappets and Cams, cheapest and best Blake Improved Rock Crushers and Automatic Ore Feeders, Superior Amalgamating Pans with wood or iron sides.

PANS FOR TREATING GOLD ONLY, Settlers, Clean-Up Pans, Retorts, Furnaces, Dump Cars, Hoisting Machinery, Cages, Landing Dogs, etc.

CORLISS, MEYER'S CUT-OFF AND BALL'S PATENT VALVE Engines of extra strength and durability.

STEEL BOILERS of Two Sheets only, Steel Economic Boilers, combining with the safety, durability and economy of the Stationary Boiler, the convenience and portability of the Portable. It occupies but little space, and is the best and cheapest boiler ever made.

WE ALSO MANUFACTURE SAW MILL MACHINERY.

We are also Sole Agents for the Gordon and Maxwell Steam Pumping Machinery, and carry a full stock of all kinds of Mill Supplies, including the

Albany Lubricating Compound and Oils.

Pacific Machinery Depot.

...SOLE MANUFACTURERS OF...

KENDALL'S PATENT QUARTZ MILLS.

Having renewed our contract on more advantageous terms with Mr. S. Kendall for the manufacture of his Patent Quartz Mill, we are now enabled to offer these mills at GREATLY REDUCED PRICES. Having made and sold these mills for the past five years, we know their merits, and know that they have given perfect satisfaction to purchasers, as numbers of commendatory testimonials prove. We feel confident, therefore, that at the prices we are now prepared to offer them, there is placed within the reach of all a light, cheap, and durable mill that will do all that claimed for it and give entire satisfaction.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et al.

Patents furnished upon application to

JOSHUA HENDY MACHINE WORKS,

39 to 51 Fremont St., San Francisco, Cal.

This cut represents our

IMPROVED
HYDRAULIC
MACHINE.

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on the machines made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List.

HOSKIN & CO., Marysville, Cal.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over other Valves and Ounce Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be discarded from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1830 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

This paper is printed with Ink Manufactured by Charles Eneu Johnson & Co., 500 South 10th St., Philadelphia. Branch Office—47 Rose St., New York, and 40 La Salle St., Chicago. Agent for the Pacific Coast—Joseph H. Dorety, 529 Commercial St., S. F.

Important Notice to Gold Miners Using Silver Plated Amalgamating Plates.

Mining men are cautioned against purchasing inferior quality of silver-plated mining plates now being manufactured and sold here in this city. The plates have proved very defective, the silver having no adherence to the copper, and assays showing great deficiency in amount of silver guaranteed.

There have been many complaints from purchasers. The delay, damage, loss of time, labor and money, caused by these defective plates, amount to considerable.

Good plates can be furnished at the same price these poor plates cost.

Mining men should purchase their mining plates only from a reliable house, having a reputation to maintain, and who can furnish genuine first-class references.

The San Francisco Plating Works, E. G. Denniston proprietor, 653 and 655 Mission street, have been manufacturing silver plated amalgamating plates for the past 18 years, and have filled over 3000 orders during that time, furnishing plates to all the prominent mining companies on the Pacific Coast. His plates are used in every mining camp. The great success of Mr. Denniston's plates is owing to perfect knowledge of the business, best modern facilities, and skilled workmen.

Perfect adherence of silver to the copper, and full weight of silver is positively guaranteed on every order. These plates have always proved durable and satisfactory in every particular.

All medals ever awarded for mining plates on the Pacific Coast were to Mr. Denniston. No gold medal was ever awarded for mining plates here. Parties advertising "gold medal awarded" make a mistake. The report of Mechanics' Institute Fair is good authority on these points.

Mining men are cordially invited to correspond with, or to visit the Plating works.

Lowest estimates furnished for sets of plates for any size quartz mills.

San Francisco Gold, Silver and Nickel Plating Works, 653 and 655 Mission street, San Francisco, Cal., E. G. Denniston, proprietor.

Mining Share Market.

There is very little new or particularly interesting to note from the Comstock, which mining center generally rules our mining share market here. There is supposed to be an ore body in the Hale and Norcross about and above the top of the winze on the 3000 level. This ore body was what the deep winze was sunk into, and which was subsequently followed down to the 3000 level. In chambering out for the boisterous works of this winze a large amount of fair-grade ore was worked, from which three fine silver bricks were produced; therefore, the management would like to get out some more of the same kind. They are raising and stopping out ore at the point designated, and will probably follow the ore vein up to the 2900 level, extracting the ore for milling. Some of the ore above the roof of this level, being stoped out, shows very well in both sulphurets and chloride, and may eventually develop into a good paying ore body. The mineral indications tend toward the belief that the much-coveted ore body is not far off. At any rate, good and efficient work is being done by the company with that end in view. The diamond drill, boring ahead at the north end of the 3000 level, has developed nothing good thus far, notwithstanding all rumors to the contrary.

The low-grade bonanzas of the north and south ends of the lode, in the Consolidated California and Virginia, and the Yellow Jacket, Kentucky, Crown Point and Belcher, are rolling out their regular daily contributions toward keeping the mills on Carson river steadily running, and considerable ore is being produced by outside mines. A large amount of dead prospecting work is being done at all points along the lode in the old mines.

THE ROLLER ORE FEEDER

[Patented May 23, 1882.]

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repair.

MACHINERY AND CASTINGS**MINING, HOISTING, SAW MILL AND HYDRAULIC PLANTS
LOCCING, PORTABLE, STATIONARY, MARINE
AND LOCOMOTIVE ENGINES,****AC'TS DYER CANNON BALL QUARTZ MILL**

222 & 224 FREMONT STREET. SAN FRANCISCO.

WANTED.**Situation by a Competent Chemist.**

Graduate of the Imperial Polytechnic Institute at Graz, Austria. Expert analyst, assayer, technologist and metallurgist. Would also go to Spanish America. Address care of F. SUSTERSIC, Big Spring, Howard County, Texas.

A CHANGE OF POSITION DESIRED.

A first-class Chemist and Mineralogist, at present Superintendent of a mining and milling company in California, wants to change his position. Besides being expert in assaying, as well as analytical chemistry, he has great experience in mining and reducing silver and gold ores. He would prefer a position in a refinery or reduction works. He can give first-class references. Address this office under A. L., 1700.

American Exchange Hotel,
SANSOME STREET,

Opposite Wells, Fargo & Co.'s Express, one door from Bank of California, SAN FRANCISCO.

This Hotel is in the very center of this business portion of the city. The traveling public will find this to be the most convenient as well as the most comfortable and respectable Family Hotel in the city.

Board and Room, \$1.00, \$1.25 and \$1.50
PER DAY, ACCORDING TO ROOM.

Hot and Cold Baths Free. None but most obliging white labor employed. Free Coach to and from the Hotel.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS!
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco. As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement. The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them. Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for. N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished in order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE FRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH of the YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves ALL THE AMALGAM GOLD and SILVER that ESCAPES THE BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

SAN FRANCISCO, SATURDAY, DECEMBER 19, 1885.

VOLUME LI
Number 25.

The State University and Its President.

There was general satisfaction expressed when the Regents of the State University chose Prof. Edward S. Holden, of Wisconsin, President of the institution. The choice was made with due care and deliberation, for there was time to make full inquiry and examination, and of a number of available candidates one was chosen whose talent and learning are attested by his scientific work, whose executive ability has shone clearly in the performance of the many trusts placed upon him; whose manliness and geniality are vouched for by those who have known him longest and best, and who comes to his important work upon the Pacific Coast in the full vigor of middle age. Knowing the interest of our readers in the welfare of the University, and their wish to become acquainted as far as possible with the President lately chosen to guide its destinies, we have engraved the portrait of Prof. Holden, which appears upon this page. In preparing a descriptive article to accompany the engraving we shall draw upon various sources of information which are available, and largely from a sketch prepared for the *Call* by Dr. J. H. C. Bonte, Secretary of the Board of Regents.

Edward Singleton Holden, passed his youth in St. Louis, where his unusual gifts of character and intelligence attracted the notice of Chauvenet, who was by general consent the first of American mathematicians with perhaps a single exception. He entered Washington University, of which his distinguished teacher was then chancellor, and graduated from its scientific department as B. S., with the highest distinction, in 1866. During the period of some five years or more that he passed in study at this institution he also did an important portion of the work in the classical course. His unusual powers and attainments in mathematics at this early period (he was only 18 at graduation) led his great teacher to form the highest expectations of him. These were shared by his other instructors and his acquaintances generally.

In the purpose of making a mathematical career he now secured an appointment as cadet in the United States Military Academy. Here he graduated in the foremost rank in 1870. The exceptional extent of the preparation for the West Point course, which his college graduation and his rare opportunities which a great mathematical master-mind had given him, enabled him to devote an unusual amount of time outside of his class routine to the private mathematical studies that formed his absorbing pursuit. He was Second-lieutenant of the Fourth United States Artillery from 1870 to 1872, when he became Second-lieutenant, United States Corps of Engineers. In 1873 he resigned, and was commissioned Professor of Mathematics in the United States Navy, which commission he resigned in June, 1882. He was Assistant Professor of Natural and Experimental Philosophy at West Point, 1871-72, and Instructor in Practical Military Engineering, 1872-73. In 1873 he was appointed Astronomer of the United States Naval Observatory at Washington. He was there long in charge of the great twenty-six-inch equatorial. As an astronomer, he is ranked among our ablest, and the value of his work is recognized in all quarters of the scientific world. His investigations upon comets and their constitution are regarded as having exceptional value. Other astronomical researches

in which he has been engaged with noticeable success are the distribution of the stars and the rectification of important star catalogues. In the former, he has carried on laborious observations and reductions in correction or reversal of the long-accepted hypothesis of the elder Herschel, that star-distribution, taking the celestial regions as a whole, is quite uniform. Professor Holden's results tend, on the con-

work: During the five years of Prof. Holden's administration, three volumes of the publications of the Washburn Observatory have been printed, and a fourth volume is ready for the printer. The astronomers have discovered and measured many new double stars, new nebulae, etc., and have lately been engaged in determining the positions of 303 fundamental stars for the southern zones of the *Astronomische Gesellschaft*. In this work they have been aided by an appropriation from the National Academy of

manent endowment fund, the interest from which will be employed in maintaining it. Prof. Holden superintended the mounting of the instruments at the Lick Observatory. These have mainly been manufactured in Europe, and they are all of the most modern design, and the best calculated to perform the work required of them.

Professor Holden is well known as a writer in the field of his favorite sciences, partly as the joint author, with Professor Simon Newcomb, of notable mathematical and astronomical textbooks, but in a more important sense as an independent author. Besides his original researches, he has given to the public a life of Sir William Herschel, a work based on original materials previously inaccessible, and distinguished by every merit proper to the biography of a man of science. In this, as in all his writings he shows himself, not only the master of his technical specialty, but the man of large general culture, and the elegant literary scholar. By this, what is a rather rare conjunction of knowledge and appreciation of both science and letters, he seems peculiarly fitted to serve the complex needs of our University, in the whole compass of its various departments. In a University, as the growth of the age has now reconstituted it, there is an essential requirement that its President should be a competent critic of the work done in its scientific side, and consequently, that he should be himself an expert in some commanding science; but it is, if possible, of still greater importance that he should be a competent appreciator of the ends and means of purely literary culture, and a hearty lover of the permanent interests of human nature, as involved in the pursuit of letters, art, philosophy and character for their own sake. The Regents and the State are to be congratulated on their fortunate selection of a man who unites these qualifications in so decided a degree.

Professor Holden's disciplinary and administrative experience, not only as an officer in the successful command of men, but as chief in charge of assistants engaged in scientific duties of the greatest importance, involving not only the most thorough disciplinary arrangements, but careful financial adjustments as well, furnishes an assuring presumption that he will be able to deal, in a temper at once firm and judicious, with the administrative problems of which, to say the least, his hands will be full.

As a man, he is said by those who enjoy his acquaintance, to unite decision and clearness of purpose with suavity and approachableness. His temper is even, but manly and direct, and his bearing is characterized by tact and geniality. He married Miss Mary Chauvenet, the daughter of his early teacher and friend.

In connection with mention of the new President it will be timely to give some general information of the present condition of the University. The annual report of Secretary Bonte, which has been published by the State Printer, contains many interesting facts in this connection. We collate a few of them. The report shows the real property, funds and endowments of the University to aggregate in value over \$3,000,000, including a State endowment fund of \$811,500; United States endowment, \$492,000; D. O. Mills' endowment, \$75,000; Brayton fund, \$90,155; Reese Library fund, \$50,000; University site and building, \$1,000,000; Lick fund and observatory, \$700,000; Toland property, \$15,000; Hasting endowment, \$100,000.

EDWARD S. HOLDEN, PRESIDENT OF THE STATE UNIVERSITY.

trary, to show the decided non-uniformity of the general distribution.

In 1882 he conducted the Government expedition to the Southern Pacific to observe the transit of Venus. The work and results of this expedition are regarded as of the highest character. A similar quality is recognized in those of the Government party, likewise in his charge, sent to Colorado in 1878, to observe the total eclipse of the sun, with a view, particularly, to ascertain the nature of the corona. In 1881 he was appointed professor of astronomy in the University of Wisconsin, and Director of the Washburn Observatory at Madison in that State. There he has since continued, engaged, largely, in his researches on comets and star distribution.

The Wisconsin State Journal says of his

Sciences, and by a liberal gift of money from O. H. Ingram, of Eau Claire. This work is nearly done, and will be printed in the forthcoming volume of publications. A number of important researches on the latitude of the observatory, on the astronomical refraction, etc., are far advanced, but must be left to be completed by Prof. Holden's successor."

His great astronomical attainments and practical knowledge cannot fail to be of the most distinguished service to the Lick Observatory when, as in the course of the next two years it probably will be, it is completed and handed over, as Mr. Lick's will requires, to the Regents of the University. As its director, there is every reason to anticipate for Prof. Holden a record of the highest order. The observatory, fully equipped, is expected to entail an expenditure of \$400,000, leaving \$300,000 of a per-

CORRESPONDENCE.

Helena, Montana.

[Written for PRESS by Our Traveling Correspondent,
R. G. HUSTON.]

Helena is the present capital and metropolis of Montana Territory. For many of the earlier and prosperous years of the placer mining interests, it was the grand center of supplies, and consequently of the whole territory as it paid tribute to Helena's prosperity. Whatever might be the want of an outside mining camp they either were compelled to go to Helena to get it or send for it East or West as the case might be; it came through Helena and an unparalleled era of prosperity was the natural result. At present the largest portion of the accumulated wealth of 20 odd years is now centered in Helena. Whenever you meet an old Montanian he will refer you with pride to the capital city as the richest city of its size in the Union. Whilst I am not at this moment conversant enough with statistics to know whether such is the fact I am willing to give them the benefit of this doubt, as I am satisfied that there is a vast amount of wealth aggregated here. Without confining my attention to small improvements, I have seen where \$1,000,000 has been expended in the past year in first-class improvements, notably, the Masonic Temple, the Grand Central Hotel, Union Block, S. T. Hauser's and D. A. G. Flowen's private residences. Either of these mentioned are structures that would do credit to any of our Eastern or Western metropolitan towns of many times the population of Helena. The surrounding country is developing in such a manner that the future of Helena is assured, as very many of the steady, regular paying quartz mines are within the short distance of 25 or 30 miles. As they are compelled to draw supplies through the town, they thus will contribute their regular ratio to the prosperity. The agricultural interests are convenient. Prickly Pear valley is within a stone's throw, as it were, and 20 to 30 miles to the eastward is the Missouri valley, with its tributaries of Confederate, Duck Creek, Ray Creek, and Deep, on the east side, and Beaver, Warm Spring Creek and Crow Creek on the west side, all of which find their market in Helena.

The educational interests are well looked after in Helena, having one large graded school building erected in 1875, at an expense of \$25,000. It contains, besides an assembly-room, seven division rooms, and has a seating capacity of 600. Since that time the growth of the town and convenience of the scholars have compelled them from time to time to erect additional buildings in different parts of the town until I should think that the capacity was fully doubled.

The Catholic fathers also have a school for boys, and the sisters a seminary for girls. There was a classical school established some two years ago. The object of the school was to place within the reach of the youth of Montana many of the advantages the colleges of the older States offer.

The Helena Commercial College was established about the same time, and is in a prosperous condition.

As to banks, the First National was established in 1866 by S. T. Hauser & Co. This is the oldest and largest banking institution of the Territory, and this year reported as resources \$2,825,556.12, which shows no mean proportions for a comparatively new country. The Merchants' National reports its resources \$944,663.53, and the Montana National and United States Depository \$862,903.19—a good showing for the financial portion of the community.

The United States assay office I was unable to get statistics from, as at the time I was in Helena the change of administration was taking place and I could not bother them then.

This place is well supplied with first-class hotels, having three very good ones, each of which is ably managed—the Cosmopolitan by Schwab & Zimmermann, the Grand Central by Reed & Riuda, the Merchants' by O'Brien & Son.

The fraternal orders are all represented, and in a flourishing condition; as are most of the different religious sects, without exception. They worship each one in their own edifice, showing that in the haste to amass wealth they are not disposed to neglect their immortal souls.

The Helena Gaslight and Coke Co., supplying consumers with a good article of gas and at fair rates, are doing, I think, a lucrative business. The Electric Light and Power Co. are having a fair share of business, and are giving general satisfaction. The city is provided with an efficient fire department and two steam fire engines that are always on hand when a fire alarm is sounded, and show that they are fully alive to the fact that they do not want their fair town devastated by fire, as it has been several times. I have seen it twice burnt myself, when the burnt territory represented more value than the portions remaining. It is well for them to be on the alert.

The city is incorporated and is governed by a mayor and the usual amount of aldermen and officials that are necessary to carry on a well regulated and well behaved community. There

are a great many cozy, pleasant houses built up here, mostly of brick, and surrounded by well kept lawns, and at this season (the 20th of November) plenty of flowers have escaped Jack Frost's attentions, a fact that perhaps is surprising to Californians, as they always connect Montana with cold weather. I did not succeed in interesting many in Helena in the PRESS, but I must say that whenever the railroad reaches a town I have a large amount of sympathy for the people, as the newspaper men are very numerous, and the more inaccessible a place is the better list I am sure to get; for when a man has one of those fellows after him every day he is not always good-natured, and once in a while I run across a case where they utterly fail to be civil, but have to excuse them on account of the number of such attacks they must have during a season.

The assessed valuation of property of the county is nearly \$8,000,000, that of Helena alone being near \$6,000,000. The city has outgrown her old courthouse which we old Montanians used to point to with a large amount of local pride. The contractors are now at work erecting one that is to cost \$150,000. Brick and granite foundation, brick, iron and brownstone above. This will certainly be a credit to the city when completed, which will be some time next season, unless something should happen to prolong it indefinitely, after the fashion of the City Hall in San Francisco. Let us devoutly hope that no calamity of that kind will overtake Helena in her courthouse speculation.

They have an organization of Montana pioneers, the spirit of imitation I suppose, as California originated that idea; but they have quite a large organization and no doubt the old-timers, as they are called, will derive a great amount of comfort from it, by meeting together and fighting their old battles over again in more comfortable quarters than they were used to in the earlier days of settlement of Virginian or Alder Gulch and Last Chance and many others discovered about the same time.

Oro Fino District, Calaveras Co.

[From Our Regular Correspondent, FRANK M. OCHOA.]

As this new mining district seems to be attracting considerable attention among mining men and capitalists, I will give a brief description of it. It is bounded on the north and east by the once celebrated Blue Mountain district, and lays on the westerly flank of the Blue Mountain range, at an average altitude of 3000 feet. Its southerly boundary is the Railroad district with West Point district on the west. Unlike the latter district, the formation of which is composed of granite, syenite and trap, fissured and cross fissured by metalliferous quartz veins, which in turn, at a date subsequent to their formation, have been bisected by a system of fissures filled with eruptive rocks.

The ore-bearing veins of the new district we find encased in a highly metamorphosed slate, with a northerly and southerly strike (stratification), carrying longitudinal fissures filled with trachyte, which forms the nucleus or core of the metal-bearing portion of the vein (the dyke proper carrying no values).

On both sides, however, of these dykes gold-bearing quartz is found of an extraordinary high tenor, and in many places the slates are auriferous for a considerable distance from the matrix proper. The formation being of a soft, friable nature, and the veins heavily mineralized, surface decomposition has taken place to so great an extent that the ore-bearing lodes rarely crop, and are known as "blind veins," with but little float to guide the prospector—accounting for this region having been ignored as a gold-producer to this recent date.

During the past summer, however, attention has been attracted to it, miners and prospectors flocked in, and the new district formed. A great number of locations have been made, some of them giving promise of provoking valuable mines. The most prominent is the "Fine Gold," recently purchased by Haggin & Kervin. This mine is an old discovery, and has been feebly but successfully worked by the owners, John and Baptiste Guillemaigne (Frenchmen) for several years. The vein was four feet and opened by a shaft and adit level, a small primitive arastra (entirely axe made) with water for a motor was the milling machinery used. The ores were free, and paid from \$12 to \$20 per ton, results covering all expenses for development. Through the assistance of Messrs. Laus & Severance as promoters, the property was sold to the present owners. Suitable hoisting works have been erected, and the mine is being systematically developed by a working shaft. A 10-stamp mill is in process of construction, and at an early date will be pounding away on the ores of the mine, which are said to be rapidly improving in value as depth is attained. The north and south extensions of this mine have been handed by Henry Janin, of San Francisco, who proposes developing them.

These mines are situated on the south bank of the south fork of the Mokelumne river. Three miles distant in a northeasterly direction on the Licking Fork an important discovery has been made by the Cook brothers, and known as the "Oro Fino." As yet the property is only a prospect, but it is a remarkably good one. A 30-foot shaft and a 20-foot drift has developed a four-foot vein of great promise. The average

ores of the vein show an assay value of \$41 per ton. They are, however base, and will have to be treated by chlorination. In the vicinity of this vein we find the Golden Harvest, owned by Gryalva & Severance. The mine has been developed by shaft; the ores are as yet said to be low-grade; vein three feet. Also, a promising discovery recently made on Groves' ranch; vein four feet; ore \$7 to \$8 per ton developed by shaft; mine so situated that it can be developed and worked from an adit to a considerable depth and the ores milled by water power. Groves' ranch is situated on the broad bottom lands of Licking Fork at the present head of wagon-road navigation. It is the stopping place where the tired traveler feels like taking a rest, and partaking of the hospitality and generous cheer of mine host Fred. Groves and his amiable daughter, Miss Quickstep, who makes it generally pleasant for the guests. Licking Fork is celebrated for its mountain trout, but Fred. Groves' three fish ponds are swarming with carp, and our lady hostess cooks them to a turn. Notwithstanding popular prejudice, they make a very toothsome pan fish. Mine host Fred prides himself on his blooded stock and brood mares which he pastures on his broad fields of alfalfa; but his particular weakness is a patch of Broddinug cabbages. And such cabbages—great solid heads, round, square and oblong, many of them weighing 40 pounds! Let the reader imagine half an acre of sauerkraut—and Fred is an artist in manufacturing it, which he supplies to his patrons far and near. The Groves ranch is the central point of the district, and will be an important point for quartz mills and reduction works, should the newly discovered mines go to the deep and carry their ores.

This point is accessible at all seasons of the year by wagon road. But little snow falls. The range is heavily timbered with spruce and the several varieties of pines and oak. The streams never fail to furnish water for power. The water shed of this section is drained by Licking Fork, and branches of the middle and south forks of the Mokelumne river. The mountains are gently sloping and are not broken up by irregular and precipitous canyons. The climate is temperate and healthy, with no extremes of heat and cold. There is no malaria. The scenery is picturesque, and at the proper season there is wild game, fish, flesh and fowl in abundance.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

TILE-SECTIONS BETWEEN WALLS, JOINTS, &c.—Wm. F. Higgins, S. F., No. 331,500, dated Dec. 1, 1885. This invention consists in a new and useful improvement on the shape and construction of the various tiles which comprise a section between walls, joints, etc.

GANG PLOW.—David M. Johnston, Stockton, No. 331,503. Dated Dec. 1, 1885. This invention consists in an improved construction of the etandards, a means for securing them adjustably to the frame, and also relates to the wheels by which the plow frame is supported; the means of raising and lowering either the front or rear plows, or the whole line, and a means by which the wheels may be allowed to run as caster-wheels, or by which they may be caused to turn on fixed axles.

PIPE-TONGS.—Henry F. W. Sohst, S. F., No. 331,456, dated Dec. 1, 1885. The object of this invention is to provide a simple and effective means adapted to secure different sizes of pipes and to grip them without danger of slipping. The invention relates to that class of tongs in which a fixed jaw is made integral with the stock or handle and a swinging jaw is pivoted to the fixed jaw; and it consists in the novel construction of the pivoted jaw, its arrangement with relation to the fixed jaw, and a spring for the said pivoted jaw.

DOVETAILING MACHINE.—L. P. Garcin, S. F. No. 331,491. Dated Dec. 1, 1885. This apparatus is especially applicable to cutting dovetail grooves on the edges or sides of strips of wood. It consists of a saw or cutter, the arbor of which is journaled in a frame, said frame swinging about trunnions fixed to a plate or table, over which the article to be dovetailed passes, and these trunnions form the center from which the sides of the dovetailed cut diverge. The arbor is adjustable on its frame to vary the depth of the cut.

SAW-MILL SET-WORKS.—D. L. Harbach, S. F. Assignor to Tatum & Bowen. No. 330,020. Dated Nov. 10, 1883. This is an improvement in setting the saw-mill log on the head-block. The invention consists in the power devices, by which the ordinary or main knees of the head-block are adjusted, in peculiar opposing knees, by which the log is stopped, and the mechanism for operating said knees. The object of the invention is to provide a single and effective mechanism for operating the various setting-knees.

HAIR CLIPPING MACHINE.—C. K. Whittier and John H. Donlon, San Francisco, No. 330,535. Dated Nov. 17, 1885. This hair clipper consists of a curved plate secured to or formed with the under side of the comb plate and acting as a bearing on which the head of the machine is adapted to rock. The object of the in-

vention is to enable the operator to graduate the length of the cut, not by a fixed gauge requiring a stoppage of the operation to adjust the gauge, but by a rocking bearing which permits a graduation of the length of the cut during the operation, while the machine is continuing its work, and on any portion of the hair surface. This improvement may be applied on any hair clipping machine.

CORE-MAKING MACHINE.—Richard Savage, S. F. No. 329,959. Dated Nov. 10, 1885. This is an improved apparatus for manufacturing cores from sand for casting purposes. It consists of a belt passing over drums or rollers at the upper or lower ends, and provided with projections, teeth or corrugations, so that when caused to travel rapidly it carries the sand downward and discharges it upon the core-hair with any desired speed and force. This belt may have a cover or directing chute in which the sand is received from a hopper or receptacle above a toothed or flanged roller, revolving in the outlet of the receptacle to regulate the flow of sand, and a means for cleaning the teeth or flanges of the roller as it revolves. It also consists in a regulating gate by which the supply passing through the discharge may be regulated. The whole of the belt or carrier is caused to travel, thus giving all the sand upon it an impetus corresponding with its own velocity of movement.

BROODER FOR CHICKENS.—Geo. B. Bayley, Oakland, No. 330,547. Dated Nov. 17, 1885. This brooder for young chickens consists in a means for supplying a requisite and equable temperature, and a space where the chickens may congregate, and in which they may be protected from wind and cold. It also consists of a peculiarly shaped chamber, into which the heat is admitted and distributed from below to the plate or surface upon which the chickens may congregate, a covering to inclose the chamber, with suitable ventilating spaces, and in certain details of construction. In the ordinary construction of brooders, which are heated from above, and have no extension from the source of heat, as this one has, the chickens will crowd to the sides and corners should there be too much heat, and the weaker ones will be trampled to death. It is claimed there will be no crowding in this brooder, since the heat is from below the chickens; will crouch and distribute themselves on the warm surface; and as it is colder at the sides will not crowd to the corners.

HARVESTER.—John Hay, Tracy, San Joaquin Co. No. 330,978. Dated Nov. 24, 1884. The invention relates to a harvesting machine of that class in which the apparatus for shading or cutting the grain is combined with the thrashing and cleaning machinery, so as to be drawn about the field and cut, thrash and clean the grain in a single continuous operation. It consists of a header mounted upon bearing-wheels, the axle or shaft of which extends directly through into the thrasher, which is supported at one side of the header, a joint connection in said shaft, so that the independent movement of the header and thrasher over uneven ground will be provided for, and the two supported upon three wheels in line, and a draper or canvas belt upon which the cut grass falls, and by which it is delivered by the thrasher, said draper having a cutting mechanism attached to its front edge, a means for conveying the thrashed straw and grain upward and backward from the thrashed cylinder and separating the grain from the straw, and in certain details of construction.

FEED CASE FOR MAGAZINE GUNS.—John C. Kilton, S. F., No. 331,244. Dated Nov. 24, 1885. This is a paper case for packing original ammunition, and a means by which said case may be directly attached to the stock or barrel of the gun, the case becoming a temporary magazine, so that the ammunition may be conveniently contained within the reach of the rifleman without the necessity of transferring it from one case to another. The invention is designed to meet the need felt by riflemen—that of securing a number of cartridges upon the gun or rifle entirely out of the way of the hands in manipulating the piece, and at the same time convenient to the hand, and in view. This design contemplates the putting up of all cartridges in small cases of five or ten, having metallic plates or straps fixed to each cartridge case so that the cases may be attached at once to a shoe, which is secured beneath the gun, where they will be out of the way, and at the same time ready for instant use, without the disadvantage of removing the cartridges from an original package or a belt, cartridge-box or receiver.

THE PRESS IN SIERRA COUNTY.—A correspondent writes us from Downieville, Sierra county, as follows: "Your energetic and wide-awake canvassing agent, Mr. Dennys, is here, and has succeeded, as I believed he would, in securing many new subscribers to the MINING AND SCIENTIFIC PRESS. He appears to be thoroughly interested in the good cause. You should have a large list in Downieville, as there are many here who are in duty bound to assist the leading scientific journal of the Pacific States and Territories, that so warmly espouses their mining interests. He ought, and I think will, do equally well in other Sierra towns. I think you are well represented."

MECHANICAL PROGRESS.

Steel for Structural Work.

At the meeting of the Engineers' Club of Philadelphia, on Nov. 7th, in addition to other proceedings, Mr. James Christie presented a paper upon "The Adaptation of Steel to Structural Work." The price of steel has now fallen so low, as compared with iron, that its increased use will be actively stimulated as the building industries revive. The grades and properties of the steels are so distinct and various that opinions differ much as to the adaptability of each grade for a special purpose. Hitherto engineers have favored open hearth steel on account of uniformity, but recent results obtained from Bessemer steel tend to place either make on equality. The seeming tendency is to specify what the physical properties shall be, and not how the steel shall be made. For boiler and ship plates the mildest and most ductile steel is favored. For ship's frames and beams a harder steel, up to 75,000 pounds tenacity, is frequently used. For tension members of bridges steel of 65,000 or 75,000 pounds tenacity is usually specified, and for compression members 80,000 to 90,000 pounds. Such a marked advantage occurs from the use of high-tension steel in compression members, and the danger of the sudden failure of a properly made strut is so little, that future practice will favor the use of hard steel in compression, unless the material should prove untrustworthy. In columns even as long as 40 diameters, steel of 90,000 pounds tenacity will exceed the mildest steel 35 per cent, or iron 50 per cent, in compressive resistance. The present uncertainty consists largely as to how high-tension steel will endure the manipulation usual with iron without injury. A few experiments were recently made by Mr. Christie on riveted struts of both mild and hard steel, which had been punched, straightened and riveted as usual with iron, but no indication of deterioration was found. Steel castings are now made entirely trustworthy for tensile working stresses of 10,000 to 15,000 pounds per square inch. In some portable machinery an intermittent tensile strength is applied of 15,000 pounds, sometimes rising to 20,000 pounds per square inch of section, without any evidence of weakness.

The uses of steel are rapidly enlarging. Eight thousand tons of steel castings are used in the construction of an immense block of bonding warehouses in London. Soft Bessemer steel is now largely used in boiler-making, and in a thousand other new directions steel is finding new uses. The iron age is rapidly passing away and the age of steel has taken its place.

Edging by Forging.

In a forging shop recently the smith was dressing some cold chisels and some lathe tools. It was noticed that by the help of his assistant, after drawing the tool to an edge, he cut off the very edges before hardening and tempering the tool. After observation showed that he had left an edge thickness of not less than one-sixteenth of an inch, somewhat more. The smith was an old workman, verging on being an old man; so he was asked "the reason why." In answer he took a bar of tool steel, heated and forged it, and made a chisel point. Then he hardened it, as usual, in clean water, scoured it, and drew it to a pigeon blue temper. A slight tap with a hammer drove the edge off as though it had been glass. He explained that good, high steel could not be hardened and tempered when drawn to a thin edge; that there was not material enough left in a fine edge to sustain an edge after hardening and maintain an edge after tempering. His plan was to harden and temper the solid metal and grind to an edge. Possibly his method was adapted only to "high" steel; and yet it is indisputable that when tools are forged to edge and hardened, they frequently crumble until they have been ground and worn far below the forged edge.

There are steels that will take a cutting edge without fire and water hardening. Wood working tools, as plane irons, can be hammered to temper without ever touching water; but usually tool steel is amenable to treatment for cutting purposes only by fire and water. Sometimes it is necessary to dress tools to shape by the file, and in that case the tempering must be the finishing.

An instance may be related. It was necessary to make some miniature hobbins to hold flattened gilt wire to be spun around a core of silk thread, producing a gold yarn or thread for embroidery and harding purposes. The hobbins were made of boxwood, and were so small that three of them would not weigh an ounce. They were run with great rapidity and needed to be exactly balanced, as they revolved around a central spindle. The tools for finishing these hobbins were of necessity made to accurate gauge, and after hardening and tempering could not be touched except to "finger stone" them to a polished edge. These tools were heated in the usual way, but instead of being plunged in water, were pushed through a cake of common beeswax on the top of a can of oil in which they were cooled. They required no tempering.

A mixture of beeswax and hard soap is handy for tempering small tools, or those that must be brought to edge as well as shape before being tempered. If the steel is good and has been properly handled, not overheated by the smith, very satisfactory results can be secured, even

when the tool is fairly edged down; and no after drawing to color will be required. But it is best, in ordinary work, to grind back from the hardest edge of any common machinist tool. A hammered edge—"cold tempered"—is a delusion; it will not stand for anything. Even in stone drilling it has been proved that those drills and chisels are best which are ground after the hammering. This is contrary to the old-fashioned notion, but it is really fact; a ground and polished edge is better than any that can be given by hammer, fire and water.—*Exchange.*

Boiler Compounds.

An engineer gives his experience with boilers in the *Iron Trade Review*, illustrating the same homely experience of some of our local engineers. He says: "I have no boiler compound with me, but remember being told by an old and experienced engineer at one time that he had taken oak logs and fastened them to the tubes of the boiler he used so that they were in constant contact with the water. He said they kept his boiler perfectly clean. I dammed up a small creek to form a sufficient body of water, cut down some oaks and threw them into it. As soon as we had commenced sawing I used to throw all the oak sawdust into the water also, and dug a narrow trench from it to a big barrel I sunk into the ground at a short distance from it. From the barrel I pumped direct to the boiler, and continued using this kind of water the whole six months I was there. The water was very muddy all the time, as teams were always disturbing the small stream which supplied this reservoir or pond. Yet at the end of the time mentioned, on blowing out the boiler, I found it as bright and clean as when perfectly new."

He then asks the question, Can not sawdust be used to advantage?

He can demonstrate this question himself by first leaching the sawdust and using the water therefrom. When done with this, we advise him to take the bark from the oak logs and leach it, using much smaller quantities to mix with water from the well or pond, and see if this is not more effective. The sawdust from oak wood may do it, and will, if it contains enough of the same principle as the bark yields.

Our conclusions are from the experience of some of the boys who claim to have tried, and are supported by charges recently made that a local boiler cleaner manufacturing company was collecting tan-bark liquor and harreling it for sale to engineers at \$1 per gallon. It was probably this fact that led to the experiments which are given above.

AXE MANUFACTURE.—A new mode of forming the cutting edge of an axe has been brought out by H. Hammond, of New Haven, Conn. In place of upsetting the edge by a hammer, it is sheared off on the desired line by any suitable shearing mechanism. The shearing operation leaves the metal in a state of uniform density and undisturbed crystallization, while the upsetting operation is said to leave the metal in a state of variant density and broken crystallization. This variant density results from the varying number and force of the blows. The claim of the patent obtained for this invention covers the process of forming the edge of the axe blade, preparatory to grinding, by shearing off the blade on the line of the proposed edge.

HARDENING STEEL.—Mr. Hammond, at the late meeting of the Mechanical Engineers, in Boston, in a paper read before that body, referred to the difficulties experienced in hardening steel, and remarked that the film of steam formed when the piece to be hardened is dipped into water very probably exercised an important influence on the result. This film, being of varying thickness, would naturally give rise to varying effects. In hardening thick steel plates he found running water to be much to be preferred. Mr. Hammond also spoke of the difficulty of obtaining sound steel castings, and some methods which he had found to yield good results.

BENEFIT OF MACHINERY.—The days of machinery, remarks a contemporary, have been for the poor man days of home-making and home-making comforts, as no other days ever were. If machinery has given the rich man luxuries, it has given the poor man the necessities and comforts of habitation, and clothing and travel, such as he never had before. The printing press, especially, is the man's servant and benefactor, scattering abroad our intellectual wealth, raising all to an intellectual level and hindering all into one whole.

PRIMING.—The worst defect a boiler can have is a disposition to prime; in other words, to send water as well as steam to the engine. Whether a boiler primes much or little, the defect is serious. Priming is in conventional terms nothing more than boiling over. The steam, as it is generated, instead of escaping freely from the water, is entangled with it, and carries over in its grasp a certain portion of the fluid.

THE POWER HAMMERS made in the United States enjoy a high reputation abroad, if we may judge from the frequent orders received for them by the manufacturers. We see it stated that Sweden has been ordering Vulcan power hammers from the firm of Duncan & Co., of Bellefonte, Pa., and that orders for them are being constantly received from other foreign countries.

SCIENTIFIC PROGRESS.

The Moon's Heat.

At the Albany meeting of the National Academy of Sciences, Professor Langley reported on the progress of his remarkable researches with the bolometer, by which he has so greatly extended our notions of the invisible spectrum. This time he dealt with the lunar spectrum, and estimated the heat derived from the unilluminated moon. Rosse had estimated the temperature of the moon's surface as from 200° to 500° F. By studying the moon at its full with a rock-salt prism obtained only after repeated failures, and which from its nature had already required replenishing seven times, each time necessitating a new determination of its constants, he had succeeded on repeated occasions in securing a spectrum which showed two curves—one according with that previously obtained in the infra red region beyond the visible portion of the solar spectrum, clearly due to reflection, and another, lying entirely beyond that, as clearly due to the moon itself, and revealing its real temperature. This, as shown by studying the spectrum of frigid masses, is colder than the temperature of melting ice. By comparing the mean of the spectra obtained in summer with that of those obtained in winter, it is evident that a much greater amount of heat is received from the moon in winter than in summer. This may simply be due to the greater amount of aqueous vapor in our own atmosphere in the summer, as contrasted with the winter clarity. By directing the bolometer to the zenith and to the horizon the temperature of space has also been measured by direct experiment for the first time, and the amazing transparency of our atmosphere to radiation of the earth's heat revealed; for his experiments show that our atmosphere transmits the earth's heat more readily than the sun's.

IMPROVED TELEPHONY.—A telegraph operator in Texas has made what he claims to be so much of an improvement in the telephone that he will be able to use the ocean telegraph cables as telephone lines, and by which articulate sounds may be transmitted with about the same facility that telephoning is now carried on over the telephone wires of ordinary distances. The inventor was led to his discovery through the very simple reasoning that, if machinery and batteries of a given power can convey the sound of the voice a certain distance, more powerful machinery might transmit it further. This theory, it is stated, has been confirmed by experiments made by the inventor with enlarged instruments and machinery, the voice having been conveyed several hundreds of miles with absolute accuracy. His scheme has been placed before one of the great cable companies, which company, having examined the results achieved, has entered into an agreement for the purchase of the sole right to use his telephone, and at the same time gave him *carte blanche* to continue his experiments. Electricians of the highest standing on both sides of the Atlantic have been engaged to watch and assist in the work, which, although it has now been going on for months, has been conducted with the strictest secrecy. It is said that the deductions made from the results of the experimental instruments have convinced scientific persons overlooking the work that the final machinery will insure conversation between the two hemispheres. The money required for carrying out the undertaking is being supplied by a millionaire of world-wide fame, who expresses himself thoroughly convinced of its practicability.

TELEGRAPHING FROM MOVING TRAINS.—Mr. Phelps, the Superintendent of the Induction Telegraph Co. to the Harlem River branch of the New York, New Haven and Hartford Railroad, claims to be able to demonstrate that moving trains can become telegraph offices for the transmission and receipt of telegrams, and that it is practical, easy and feasible to govern the movements of trains in perfect safety by instantaneous telegraphy. He says: "I have lately rearranged the coil cable, placing it on the side of the car just outside the trucks and wheels, instead of horizontally under the center of the floor, and this adjustment permits us to lay the wire outside the rail on the sleepers, which diminishes the cost four-fifths, or, in other words, our property has become five times as valuable as when we placed the insulated rubber-covered wire within a box on the center of the track, midway between both rails." He believes that this telegraphing to and from a car in motion can be made to do away with the "block system" entirely.

WATER RUNNING THROUGH A SMALL HOLE.—In a paper read before the late Boston meeting of the Society of Mechanical Engineers, Mr. Oberlin Smith, of Bridgeton, N. J., in contributing to the list of unexpected things which often happen, remarked that on one occasion he made a metal cup about three eighths of an inch deep and from two to three inches in diameter, into which he wanted water to leak through a small hole in the bottom by partially submerging the cup. With a hole one-sixty-fourth inch diameter, he found that no admission of water could be effected unless the cup was submerged to a depth of more than one inch. Successive diameters of hole gave but little better results. By making the hole slightly larger at the top, however, the water

passed through readily. Thus, with a hole tapering from one-thirty-second inch in diameter at the bottom to one-sixteenth inch in diameter at the top, no great difficulty was experienced.

CONVERTING NATURAL GAS INTO ILLUMINATING GAS.—This process is said to be very simple and cheap. The following is a description of the process: Natural gas and steam are simultaneously passed at a pressure of 40 pounds into a large pipe which admits them into the machine. The gas and steam then pass up and down 60 feet of red-hot pipe, when it is superheated. They then pass into the heaters, which are filled with iron turnings heated to a cherry red, where the steam is decomposed. The gas then passes into another heated pipe, where it is carbonized. It next passes into a long coil of piping in the center of a furnace. The high heat of the furnace changes it into acetaline, which gives it its luminous property. It is then passed through a coil of gas-piping, where it is cooled, and next passes direct into the gas-holder. The process makes gas at a rapid rate, and has the merit of simplicity. It makes natural gas an illuminant of 21 candle-power, at a cost of less than 10 cents per 1000 feet.

THE TOES IN ANCIENT AND MODERN TIMES.—In a paper read before the Anthropological Institute of Great Britain, Sir J. Park Harrison has stated that, according to his observations among the English the great toe is longer than the second; but as the ancients have represented in statuary the second toe as the longer, this must have arisen from a different proportion prevailing in Greece and Italy. Barroli finds, however, as the result of 447 measurements of Italians, that 62 per cent have the great toe longer; and although it is true that, of 12 antique statues in the galleries of Florence, all but two have the second toe longer, he thinks this has arisen from a conventional feeling, which regarded that shape of the foot as more beautiful. It is found to be the case frequently that the relative length varies in the two feet. While the great toe is the longer in the majority of mankind, the case seems to be reversed in the mongoloid and negro races.

INVESTIGATING THE GULF STREAM.—Some fresh information about the Gulf stream is given by a Boston scientist. It is a stratum of warm blue water not more than 50 fathoms deep, and it flows due east at a rate that would take it to England within 100 days. Off Cape Hatteras this northward flowing stream is in the form of a fan, its three warm bands spreading out over the Atlantic surface to an aggregate breadth of 167 miles, while two cooler bands of an aggregate breadth of 52 miles are interposed between them. The innermost warm band is the one that shows the highest temperature and speed, its velocity being greatest where it is pressed laterally by the Arctic current, so that the rate of four miles per hour is occasionally observed. The peculiar blue color of the water, probably, is because the river silt washed into the gulf by the Mississippi is held in suspension.

THE SLEEP OF FISH.—An experiment has recently been tried at the Inventions Exhibition aquarium by Mr. W. August Carter with a view to discovering how far fish are prone to sleep. After close examination he found that among fresh-water fishes the roach, dace, gudgeon, carp, tench, minnow and catfish sleep periodically in common with terrestrial animals. The same instincts were found to actuate marine fish, of which the following were observed to be equally influenced by somnolence: The wrasse, conger eel, dory, dogfish, wrasse bass and all species of flat fish. Mr. Carter states that, so far as he can discover, the gold fish, pike and angler fish never sleep, but rest periodically. Desire for sleep among fish varies according to meteorological conditions. Fish do not necessarily select the night time for repose.

OBSCURE HEAT.—In a paper recently read before the Paris Academy of Sciences on the increase in the luminosity of incandescent carbons with the intensity of the electric current and the consequent temperature, and the diminution of the luminous intensity after a certain point (about 4713 degrees C.) is passed, M. F. Felix Lucas argued that it is probable that the thermic radiations, which are at first dark and then luminous, passing from red to white, ultimately go beyond the violet rays and cease to be visible.

SINKING TO GREAT DEPTHS.—A cannon-ball or any heavy substance will sink to the bottom of the ocean as fast as gravity will carry it through the water. No matter how great the pressure is at great depths from the superincumbent mass of water, the specific gravity of the water is but little greater than at the surface. Hence all substances as stone, sand, mud, clay, shells, etc., exist at great depths with but little variation, except from the effects of decreased light.

A Texas telephone experimenter claims to have perfected a magnetic telephone, the whole appliances of which are a simple transmitter and receiver and a horseshoe magnet. With this and a single wire he claims to be able to send a message around the world. He proposes to secure foreign patents before making application in this country.

SAN FRANCISCO:

Saturday Morning, Dec. 19, 1885.

TABLE OF CONTENTS.

EDITORIALS.—The State University and Its President, 401. Passing Events; Annual Expenditures on Claims; Further Discouragement; "The Rude Cable Grip on the Bridge," 404. Coal Lands; Practical Hydraulics; Zinc; Roll Feed Surface Planing Machine, 405.

ILLUSTRATIONS.—Edward S. Holden, President of State University, 401. Large Double Cylinder Feed Surface Planing Mill, 405.

CORRESPONDENCE.—Helena, Montana; Oro Fino District, Calaveras Co., 402.

MECHANICAL PROGRESS.—Steel for Structural Work; Edging by Forging; Boiler Compounds; Axe Manufacture; Hauling Soller; Benefit of Machinery; Priming, 403.

SCIENTIFIC PROGRESS.—The Moon's Heat; Improved Telegraphy; Telegraphing from Moving Trains; Water Running Through a Small Hole; Converting Natural Gas into Illuminating Gas; The Toes in Ancient and Modern Times; Investigating the Gulf Stream; The Sleep of Fish; Obscure Heat; Sinking to Great Depths, 403.

USEFUL INFORMATION.—A Lesson in Shop Management, Large or Small Engines—The Safe Slide; Antiquity of Sheep on the Earth; Neatness in the Engine Room; Boiler Insurance; Explosions in Mines, 407.

GOOD HEALTH.—Inoculation of Hydrophobia; Bitten by a Centipede; A Rapidly Growing Health Evil; A Dangerous Diet; Danger from Fig Tree Twigs, 407.

MISCELLANEOUS.—Notices of Recent Patents, 402. Practical Hydraulics, 406. Town Sites and Mineral Lands, 407.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Montana, New Mexico, Oregon, and Utah, 408-9.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board. Notices of Meetings, Assessments, Dividends, and Bullion Shipments, 412.

Business Announcements.

Assayer—C. H. Aaron, Nogales, Arizona.
New Traction Motor—D. N. Dilla, Oakland.
Photography—Prof. E. Longley, Los Angeles.
Insurance Agents—Butler & Haldan.
Galvanic Belts—Dr. Emory L. Willard.

Passing Events.

The Big Hole placers are just now exciting the Montana mining people, reports from there indicating good prospects. In fact, some of those who have visited the mines are confident they are going to be as extensive placer mines as have ever been discovered in the Territory. Of course, claims have been taken up, and a number of miners from other camps have gone in there.

Interest in Nevada mines is just now centered in some of the districts along the Carson & Colorado railroad; notably at Hawthorne district, where the Lapanta and one or two other mines are doing remarkably well.

Oregon mines are just now attracting more attention than for many years past. The Pine Creek excitement started a sort of boom for that region, and now other portions of the State are being more carefully prospected.

Before the PRESS makes another visit to its readers Christmas will have come and gone, and we therefore wish them all, thus early, the "compliments of the season."

At Tombstone, A. T., the jury in the case of the Mountain Maid Mining Company vs. James Reilly, brought in a verdict for defendant. The action was an important test case, affecting title to a large number of town lots. The effect of the verdict is to quiet title and leave the present owners in possession.

Annual Expenditures on Claims.

For the past month or two miners in all the camps have been actively at work on their claims in fulfilling the requirements of the United States laws regarding annual expenditures on mining claims. In some cases this "assessment work" has resulted in mines being developed out of prospects. In others, it has served only to continue the ownership of undeveloped claims. The law, as a whole, has worked well, and has prevented, in a measure, one or two men holding a whole string of claims for an indefinite period without doing any work on them. It has, moreover, decided definitely as to abandonment, which was formerly one of the vexed mining law questions. Now, if a man does not do his assessment work, the claim is legally abandoned and may be relocated by any one who chooses to do so. All unpatented claims on which \$100 worth of work was not done before January 1, 1886, were forfeited and subjected to relocation, according to the old ruling of the Commissioner of Public Lands. A more recent ruling provides that in cases where owners or locators of mining claims are actually engaged in doing their annual work on January 1st, such claim is not subject to relocation, providing the owner puts in the full amount of labor required by law during said month.

There are several points in connection with this subject, to which it is proper to call the attention of miners at the present time. For instance, Congress has expressly provided that money which has been expended in running a tunnel for the purpose of developing one or more lodes owned by certain persons or a company is considered as expended on the lode. The person or company is not therefore required to perform work on the surface of the lodes, in order to hold them. In other words, the work may be from the surface or by tunnels, as the owner desires.

Expenditures may be, of course, made by an agent, and not necessarily by the owner or owners of the claim.

It must be remembered also that the fact that a large expenditure has been made on a claim in the past will not relieve a claimant from the necessity of performing the required annual labor.

A party also contributes his proportion of the required (annual expenditure) expenditures can retain his interest in the mine. If a party fails to contribute his proportion of the actual expenditures upon a claim, the remedy must be sought outside the Land Department.

The land office has ruled that the claim is not subject to relocation as abandoned ground, until the expiration of the year next succeeding that for which annual expenditure has been made.

It is held that labor performed or money expended upon a mining claim, prior to the first day of January succeeding the date of location thereof, will not be considered as a part of or applied upon the first annual expenditure required by law. Thus, upon a claim located at any time during the year 1884, the period within which the labor must be performed commences January 1, 1885, and during the calendar year 1885 the expenditures must be made, or the claim will be subject to relocation on and after January 1, 1886. The expenditures must afterwards be done annually by the calendar year.

It must also be remembered that if the assessment work is not done within the year, the claim is subject to relocation by any one, provided that the original locators, their heirs, assigns or legal representatives have not resumed work upon the claim after failure and before such location. In other words, if the original locators or owners have begun work on the 1st of January, before others have located the claim, they can, of course, hold it.

By decision of the Honorable Secretary of the Interior, dated March 4, 1879, annual expenditures are not required subject to entry for patent, the date of issuing patent certificates being the date contemplated by statute. That is to say, that after entry for patent the claim is not subject to relocation for abandonment or failure to make annual expenditures.

The law provides for getting rid of co-owners who do not pay their share of the expenditures. Upon the failure of any one or several co-owners to contribute his proportion of the expenditures necessary to hold the claim or claims held in ownership in common, the co-owners who have performed the labor or spent the

money for it, may, at the expiration of the year, give such delinquent co-owner personal notice in writing or notice by publication in the newspaper published nearest the claim, for at least once a week for 90 days, and if, upon the expiration of 90 days after such notice in writing, or on the expiration of 180 days after the first publication of notice, the delinquent co-owner shall have failed to contribute his proportion to meet such expenditures or improvements, his interest in the claim by law passes to his co-owners who have made the expenditures or improvements.

We append three forms which miners may find use for at this time, in connection with the question of annual expenditures:

Proof of Labor.

—of—County of—, ss.

Before me the subscriber personally appeared —, who, being duly sworn, says that at least — dollars' worth of labor or improvements were performed or made upon [here describe claim], situated in — mining district, — county, — of —, during the year ending —, 188—. Such expenditure was made by or at the expense of —, owners of said claim, for the purpose of holding said claim.

[Jurat.] — (Signature).

NOTE.—The record of an affidavit like the above is prima facie evidence of the performance of such labor.

Notice of Forfeiture.

—County, —, 188—

To—(names of all parties who have record title to any portion of the mine). You are hereby notified that I have expended — dollars in labor and improvements upon the — lode (describe the claim), as will appear by certificate filed —, 188—, in the office of the Recorder of said county (or district), in order to hold said premises under the provisions of Section 2324 Revised Statutes of the United States, being the amount required to hold the same for the year ending —, 188—. And if within ninety days from the service of this notice (or within ninety days after this notice by publication), you fail or refuse to contribute your proportion of such expenditure as a co-owner, your interest in said claim will become the property of the subscriber under said Section 2324.

— (Signature).

NOTE.—At the expiration of 180 days, this notice should be recorded with the affidavit of the newspaper publisher, that the same was published for the period of ninety days, together with the affidavit of the party signing the notice to the effect that one or more of the co-owners named in the published notice have not paid their share of the expenditure. This completes the record title.

Affidavit of Failure to Contribute.

—of—County of—, ss.

—, being duly sworn, deposes and says that for the year ending —, 188—, he expended at least — dollars in labor and improvements upon the — lode [or—placer claim] (here describe the claim), to hold the same under the laws of the United States and of this — (district, Territory or State); that due notice thereof was personally served upon —, co-owners, on the — day of —, 188— (or was duly published in the —, as appears from the affidavit of the publisher thereof); and that — (of the said) co-owners have failed or refused to contribute their share of said expenditures within the time required by law.

Subscribed and sworn to before me this — day of —, 188—.

Further Discouragement.

The hydraulic miners feel discouraged in their efforts before the courts, as so many points have been decided against them. They have just received what they consider another set-back in Nevada county, where Judge Walling has granted, in the case of Hedges and Merriam against the supervisors of Yuba county and their bondsmen, a change of venue to Yuba county. The suits were brought by taxpayers of the mining portion of Yuba to restrain the supervisors there from paying out of the treasury of that county large sums of money to be used against hydraulic miners, and to recover to the county from the bondsmen of said supervisors the sum of \$13,007.08 already appropriated in that manner.

In Nevada county they think this change of venue will result in the injunction being raised on the supervisors and thus enabling the free spending of Yuba county money in forcing with increased vigor and bitterness the fight against the hydraulic miners, which has for some time lagged on account of the pending of these suits.

THE Bodie Free Press says that one of the mysteries of nature's laboratory can be fathomed by a visit to Allen's Springs, near Bridgeport, Mono county, where a vein of mineralized quartz is under process of formation.

"The Rude Cable Grip on the Bridge."

The above heads an editorial in the New York Herald in relation to the terrible accident that occurred on the Brooklyn Bridge Cable Railway on the 5th inst., by which five persons were severely injured, while many others in the crowded cars were badly scratched and bruised two or three cars being badly wrecked. The Herald further says, "the cable motor system on the Bridge is a rude mechanical appliance quite behind the age." In this the Herald is right, for the Bridge railway from the start has been a chapter of accidents. Competent cable railway engineers in this city who have examined the "system" on the Bridge have pronounced it rude in the extreme, and the appliances used have been the laughing stock of practical men who are familiar with the cable system as worked in this city.

Quoting further from the Herald, "The conductor has only partial control of his train. He can neither regulate its speed nor stop it without throwing the grip off the cable." What would he thought of such an arrangement in this city where the gripman has full control of his car at all times, and by the perfect system of brakes can stop with certainty and almost instantly, if necessary?

Whenever an accident of this kind occurs, the managers of the Bridge raise the cry that more room is wanted for handling the cars on the New York side, and have been trying for some time to have the Bridge extended across the street to City Hall Park, at a very heavy expense. This will not remedy the cable system, and these accidents will be just as liable to occur. We are informed that there is ample room to handle the cars with perfect safety when a proper cable system is applied. The whole system is wrong. The cars weigh about ten tons each, and are built strong enough to run across the continent, with wheels as large as ordinary steam roads, while they have no greater carrying capacity than the Market street cars in this city, which do not weigh over half as much. The cable cars in this city have low wheels and track brakes, as well as the ordinary wheel brakes. With the grip that is used upon the California and Sutter street lines, and the same kind of brakes, no such accidents could happen on the Brooklyn Bridge as are continually reported.

As far as room is concerned to handle the cars, there is more on the Bridge than the Market street road has at the ferry landing in this city, where we have seen seven cars started within five minutes, and here a turn-table has to be used. A train can be started here every 20 seconds if desirable. The fact is, the switching arrangement on the Bridge is about as rude as the grip. Perhaps after a few people are killed the Brooklyn Bridge Trustees will send a competent engineer here to learn something about the cable system and apply a remedy.

INYO COUNTY VIEWS.—We have been shown by Capt. J. I. M. Keeler, a fine collection of photographs of Inyo county scenery. Many of the photographs are of mountain scenery and show most remarkable formations. Those of the summit of Mount Whitney are particularly interesting to the geologist. The canyons in that part of the Sierras are precipitous and grand in the extreme. The region when better known is one which will be visited largely by tourists in search of sublime and picturesque scenery. Captain Keeler is now here for the purpose of having magic lantern slides made from these photographs. He has written, in verse, several lectures descriptive of Inyo county, which it is probable he will deliver here, as well as in the East. The object is to call the attention of the people to the resources of Inyo county, which is now thinly settled, and of which there is comparatively little known by the general public. Captain Keeler has been a resident of Inyo for some years, and has visited every portion of it, even the peaks of the highest mountains, so that he is well qualified to describe its scenery and resources.

A TON OF GOLD.—The exact value of a ton of gold is \$602,927.23. In Mr. Cadwallader's article on the "Debris Question," in last week's PRESS, he said that a ton of gold is worth over \$600,000, but the types made him say it was worth over \$6,000,000.

J. W. MACKAY went to Mexico as a tourist, not as an investor in mines.

Coal Lands.

The Secretary of the Interior has decided in an appeal case from the Land Commissioner's ruling that in case of an application to purchase coal lands under Section 2347, without having filed declaratory statement, no rights are acquired by virtue of alleged prior possession, as against adverse claimants who filed within statutory period.

The contest occurred in Wyoming. One man filed a declaratory statement June 1, 1882, another filed June 6, 1882, and still a third filed application to purchase July 24, 1882. The last one of the three kept possession, and expended \$480 in developments. He asked a hearing to determine the rights of the several parties, and, the land officers, at the hearing, decided in his favor. The U. S. Land Commissioner, however, on appeal reversed the decision, and rejected the application to purchase. He then appealed to the Secretary of the Interior. That official sustains the Commissioner and decides that the third applicant (who alleged prior possession, and filed application to purchase) acquired no rights by virtue of his alleged prior possession as against the adverse claimants, who filed their declaratory statements within the time prescribed by law.

A portion of the land applied for was within a section reserved for school lands in Wyoming.

book will be one greatly used by miners and engineers. If there are any questions connected with the subject which occur to our readers, which might be properly elucidated, the suggestions would be gladly received.

A NEW concession has been made by Mexico to the Eads' Ship Railway Co. These amendments add to this previous land grant 1,700,000 acres, the whole land concession being equal to half the area of New Jersey. Coaling stations are to be permitted at either end of the railway, to which coal from the United States, or any other foreign nation co-operating with Mexico and guaranteeing interest on the bonds of the railway company, is to be admitted free, to the exclusion of coal from all other countries. This will give a new market to the United States coal trade if Congress joins with Mexico in the guaranty upon which this bonds to build the ship railway are to be based. Mexico guarantees the payment of \$1,250,000 a year for fifteen years, provided the United States or some European nation will guarantee \$2,500,000 more for the same period. The time for completing the road has been extended to 1894.

CLIMBING OUT OF A SHAFT.—A dispatch from Mokelumne Hill, says: Saturday evening last Edward Pippin, whilst returning home from town alone, fell into one of the many abandoned shafts near the trail leading to his cabin. It being very foggy and dark, Pippin was unable to find his way, and accidentally walked into the shaft, which is about 35 feet deep and con-

Double Cylinder Roll Feed Surface Planing Machine.

The accompanying engraving illustrates a new large double cylinder roll feed surface planer. It is a marked departure in surface planing machines. It is massive and heavy, the framing of the machine being made with heavy plate sides, with internal ribs. The joints are planed, holes reamed, bolts turned, and every part constructed in the most thorough and careful manner, the object in designing this machine being to construct the most reliable and powerful roll feed surfacing machine made. Its capacity is to dress from $\frac{1}{4}$ " to 30" in width, and up to 6" in thickness.

Pressure bars are placed close to the cut upon either side of the lower cutter head; also a holding-down bar above it, by unloosing a hand nut, can be instantly swung entirely out of the way, affording ready access to the cutters. Yielding pressure bars are also arranged upon each side of the upper cutter head, that on the leaning-in side being attached to swinging arms, which allows the edges of the bar to work close to the cutters; this prevents tearing and splintering in cross-grained lumber. It can easily be raised up for gaining access to the cutters. The bar after the cut is also self-adjusting.

The upper and lower cutter heads are formed with steel lips upon their faces, have heavy cast

Zinc.

The greater part of the zinc ore used in this country is obtained as a more or less valuable by-product in the mining of lead ore, and its selling price is not controlled, either by the value of the metal it contains, or by the cost of its discovery and mining. Hence the value is subject to sudden changes, and the investment of capital in zinc mining is rendered more or less unsafe. This fact has exerted a controlling influence on the methods of mining and selling the ore, on the districts most extensively worked, on the location of the principal smelting works, and on their policy towards the ore producers. Its full importance may perhaps be obscured by the fact that lead and zinc ores are almost universally found associated together; but when the selling price of both ores is controlled by the value of the metal they contain, each bears its proper proportion to the cost of mining, and neither unduly depreciates the value of the other.

The inland location of existing mines and works in this country, as compared with the mines and works of Europe, makes them more dependent on railroad transportation, and less easily adaptable to changes in the mining and smelting centers. The metallurgy of lead is so simple that when such deposits of lead and zinc ores are discovered, the lead ores are quickly

LARGE DOUBLE CYLINDER FEED SURFACE PLANING MILL.

The Secretary says in this connection: "It will be unnecessary to discuss the question as to the effect of said reservation where sections 16 and 36 contain mineral, but no locations have been made thereon prior to survey, for the reason that in the case at bar the locations were made prior to the filing of the township plat of survey in the local land office, and your office was advised on July 30th last, that such locations prior to survey were not intended to be included in the order of suspension dated March 24, 1885."

Practical Hydraulics.

The articles on "Practical Hydraulics," by P. M. Randall, now being published in the PRESS, are worthy of careful perusal and preservation by miners and engineers. Those portions recently published devoted to the "Flow of Water Through Vertical Rectangular Orifices in Thin Partitions," and to the "Miner's Inch," are especially useful. The article this week, which embraces the subject of the miner's inch, takes up the miner's inches of different values, with some interesting tables, examples and calculations.

The clearness with which the subject is treated commends a careful perusal of the article by all interested in this branch of hydraulics. To the analyst are presented concise formulæ, and to all familiar with elementary arithmetic are presented rules and tables susceptible of easy application in practice; besides, practical examples, with their solutions simplified to the greatest extent, are given. The requirements of all classes are thus happily and fully met. Mr. Randall quotes from authorities, but the matter is largely original and presented in novel and convenient form. When printed in book form, we feel assured that the

tains about five feet of water. Pippin finding himself uninjured and standing in water up to his neck, considered it useless to attempt making himself heard, and proceeded at once to try and get out. With a pocket-knife he cut holes in the side of the shaft, which acted as steps. After falling back to the bottom about 25 times, he succeeded in reaching the surface more scared than injured. He was in the shaft over 36 hours.

BIG COPPER CONTRACT.—A dispatch from New York, dated the 16th, says: The Lake Superior companies have made contracts within the past few days with home manufacturers for a large amount of ingot copper for delivery next year. According to a good authority, 10,000,000 pounds were contracted for at 11½ cents—an advance of fully half a cent upon what moderate lots were selling for one month ago.

THE Sisters of Charity are erecting a large building on the corner of Gough and Geary streets, to be used as a technical school for girls over 14 years of age, for whom the State makes no provision. It is expected to be self-sustaining from the sale of the work of pupils.

THE Oroville Register gives an account of a young man named Henry Johnson, who is now able to go without sleep for ten days at a time, and gets along well with only four hours' sleep in a week. He says it is of no particular benefit to him, as he gets tired the same as other men and has to rest the same number of hours that they sleep.

It is stated that for three months a large pump has been at work in the Grand Central mine at Tomahstone, without diminishing the amount of water in the lower levels. It has just been discovered that the water pumped out found its way back into the mine, and was being simply handled over and over again.

steel shafts, which extend entirely through the heads, with the journals finished in the very best possible manner. The upper head remains stationary, the head raising and lowering to suit the thickness of the material. The under cylinder is easy of access for convenience to the operator, as the upper housing, carrying the pressure bar over it, is made to swing entirely out of the way. Both cutter heads are belted on each side, although the engraving shows the latter belted upon one side only. The lower cutter head runs in connecting hearings, and has a vertical adjustment with the platen or bed.

The feed rolls are large in diameter and powerfully geared, part of the train of gearing being upon each side, making the draught very uniform. The rolls are supplied with patent weighting attachment, and readily adapt themselves to varying thicknesses of material. A roll cover extends from the cylinder to the front pressure bar, entirely protecting the feed-out rolls from dust and shavings. The feed is started and stopped by means of a belt tightener operating upon the slack side of the belt, actuated by a hand lever.

The platen or bed is glided to the sides of the machine, and is raised or lowered to accommodate the thickness of material to be worked by means of a hand wheel at the end of the machine. The agents for this coast for these machines are H. P. Gregory & Co.

THE marble lately discovered in Inyo county is found to improve in quality the deeper the mountain is pierced. Samples sent to Sacramento are pronounced by experts to be equal to any ever found in Italy.

THE monthly pay-rolls for labor in the mines of Eureka district, Nevada, and at the two reduction works in town aggregate \$35,000.

made available by furnaces erected to treat them and are mined extensively; while large amounts of zinc ore are often neglected or thrown aside as worthless. The metallurgy of zinc is so complicated and expensive that it is slow to adapt itself to new localities, and the works within reach of the new ore fields have a practical monopoly of these markets. The present sources of supply in this country, according to Government authorities, may be grouped under three divisions: the Eastern, including New Jersey, Pennsylvania and Virginia; the Middle, including Wisconsin, Illinois and Tennessee; and the Western, including Missouri and Kansas.

Holiday Art Cards.

L. Prang, of Boston, gives us again (through dealers generally) the most beautiful of all specimens of Christmas and New Year art and decorative cards. The people of our whole country cannot too highly appreciate Mr. Prang's success as a superior, honorable and world renowned art publisher.

Many new productions have this year been added to his previous large list of rarely beautiful designs.

Two new folding calendars have been added to the line, one with four landscapes representing the four seasons, the other with a procession of very charming children, representing the twelve months. These are particularly useful, ornamental and desirable.

In satin art prints the line excels all previous efforts in the artistic execution of the pictures, as well as in the rich and tasteful mountings. Among the new shapes are a scroll and clover leaf, and among the material used, a very clever imitation of different kinds of wood, such as walnut, satinwood and bird's-eye-maple, which forms an artistic background to the rich and delicate satin prints.

THE Alice mine, of Montana, has paid four dividends this year, aggregating \$125,000.

PRACTICAL HYDRAULICS.

NUMBER 9.

PRINCIPLES OF HYDRAULICS.

Written for MINING AND SCIENTIFIC PRESS by P. M. RANDALL.
[COPYRIGHTED.]

On this data, the value of the statutory miner's inch, the mean coefficient of discharge being in practice .6216, is as follows:

For one second (second inch), 0.02 cubic feet.
For one minute (minute inch), 1.20 cubic feet.
For one hour (hour inch), 72.00 cubic feet.
For 24 hours (24-hour inch), 1728 cubic feet.

If a cubic foot be divided by the flow in one second, there will result the number of miner's inches whose discharge is equal to a cubic foot per second. Thus, $1 \div .02 = 50$ statutory miner's inches; that is, fifty statutory miner's inches are equal to one cubic foot flow per second.

NORTH BLOOMFIELD, ETC., MINER'S INCHES.

At the North Bloomfield, Milton and Columbia Hill hydraulic mines, the water is measured in its flow through a rectangular orifice 50 inches long, 2 inches wide, and under a pressure of 7 inches on the center of the opening. The flow per square inch of orifice, for 24 hours, due this head, as given me by Hamilton Smith, Jr., C. E., formerly chief engineer of the North Bloomfield Works, and president of the Miners' Association, is 2230 cubic feet; of which the coefficient of discharge is found to be .6064. Mr. Smith's experiments made with a module of equal dimensions under a 7-inch head, at Columbia Hill in 1874, found, as stated by Aug. J. Bowie, Jr., M. E., in an article entitled "Bowie on the Measurement and Flow of Water," found the value of the 24-hour inch to be 260.8 cubic feet, and the coefficient of discharge to be .616. Mr. Bowie, in the article referred to, gives, in addition, substantially the following data, with respect to the

SMARTSVILLE MINER'S INCH.

Height of orifice, 4 inches; head on center, 9 inches; value of 24-hour inch, 2534.4 cubic feet; coefficient of discharge, .6078.

SOUTH YUBA CANAL INCH.

Height of orifice, 2 inches; head on center, 6 inches. And with respect to a series of experiments made by himself at La Grange with an orifice 12 inches high, 12.75 inches wide, under a pressure of 6 inches on the top of the orifice, or head of one foot on the center. The mean of which experiments gave as the value of one miner's inch for 24 hours, 2159.146 cubic feet; effective coefficient of efflux, .5905. The flow through this module was assumed equal to 200 miner's inches.

A comparison shows that these coefficients of discharge approximate closely those given in Table 7, obtained on equal data. The results of these experiments also clearly show that the value of a coefficient of discharge depends, among other things, upon the form of the module. In illustration, the module being 50 inches long, 2 inches wide, the coefficient of discharge is found to be .5905. Should we estimate the effect of the difference between the given heads (7 inches and 1 foot) on the coefficients of discharge, there would result .5885 instead of .5905.

The variety of values comprised in the term, miner's inch, as employed in California, is often a source of no little annoyance and confusion. To aid in overcoming this difficulty, Table 8 prepared from Table 7, is given. Each result so obtained is a mean of the experiments of the world's ablest hydraulicians.

*The flow due the given opening, $12'' \times 12.75'' = 153$ square inches, divided by 200, has been proposed, as hereinbefore stated, as the standard miner's inch. Its adoption seems to be but local.

*This series of articles will shortly be published in book form by Dewey & Co., the MINING AND SCIENTIFIC PRESS, 252 Market St., S. F. Subscriptions will be filled in the order in which they are received.

EXAMPLES AND CALCULATIONS.

Ex. 45.—A water right location is made for 6000 miner's inches. What is the equivalent flow in cubic feet per second?

Cal. 1st.—The statutory miner's inch is estimated, as stated, under a 4-inch pressure.

By Table 8, opposite 4 inches in "head on center" column, find 49.24 miner's inches in "1 cubic foot flow per second" column, $6000 \div 49.24 = 121.6$ cubic feet.—Ans.

Cal. 2d.—For the most part in practice, 50 miner's inches measured under a 4-inch pressure, are adopted as equal to a flow of one cubic foot of water per second. This results, as shown in discussing the statutory miner's inch, from taking the mean coefficient .6216 for different heads, instead of the tabulated coefficient .632 for the given 4-inch head.

Whence, $6000 \div 50 = 120$ cubic feet.—Ans.

Ex. 46.—In a water right claim of 5000 miner's inches, measured under a 4-inch pressure, are how many North Bloomfield miner's inches—miner's inches measured under a 7-inch head?

Cal. 1st.—By Table 8, the value of a second inch, under a 4-inch head, is .0203 cubic feet flow; and the value of a second inch, under a 7-inch head, is .0269 cubic feet flow.

Whence, $.0203 \times 5000 \div .0269 = 3773$ miner's inches.—Ans.

Cal. 2d.—In the discussion of the miner's inch, it has been shown that in common practice the value of the 24-hour inch, under a 4-inch head, is 1728 cubic feet; and under a 7-inch head at North Bloomfield is 2230 cubic feet.

Whence, $1728 \times 5000 \div 2230 = 3874$ miner's inches.—Ans.

Ex. 47.—In 2000 miner's inches, through a rectangular opening 2 inches high, and under a 6-inch pressure, as employed at the South Yuba canal, are how many miner's inches flowing through a rectangular opening 4 inches high and under a 9-inch pressure, as adopted at Smartsville?

Cal. 1st.—As the result will be the same, whether the calculation be made in second, minute, hour, or 24-hour miner's inches, let the 24-hour inch be employed; then by Table 8, under a 6-inch pressure through opening 2 inches high, the value is 2152 cubic feet; and under a 9-inch pressure through opening 4 inches high, the value is 2602 cubic feet; whence, $2000 \times 2152 \div 2602 = 1654$ Smartsville miner's inches.

Cal. 2d.—Under the heading Smartsville, "Bowie on Measurement and Flow of Water," makes that miner's inch, 2534.4, due coefficient of discharge .6078, instead of .624, as adopted in Table 8.

Whence, $2000 \times 2152 \div 2534.4 = 1698$ Smartsville miner's inches.—Ans.

Cal. 3d.—Table 8 shows that the coefficient due a 6-inch head, and opening 2 inches high, is .632, and that the coefficient due a 9-inch head, and opening 4 inches high, is .624. Now, as commonly practiced, the "mean" coefficient .62 would be employed; so that, the result sought would depend upon the square root of the ratio of the given heads, 9 inches=.75 feet, and 6 inches=.5 feet; thus, by Table 5,

$$\sqrt{\frac{.5}{.75}} = \frac{.75}{.8165} = .8165.$$

$.8165 \times 2000 = 1633$ Smartsville miner's inches.—Ans.

EXAMPLES AND CALCULATIONS.

Ex. 48.—The head being 2.25 feet on the center of a circular orifice .0328 feet diameter, what is the discharge in cubic feet per second?

Cal. 1st.—Rule 27 is equally applicable to rectangular and circular orifices.

By Table 6 square root of given head 2.25 feet=.15 feet.

Area of given orifice .0323 feet diameter is equal to the square of the diameter, multiplied by .7854; $(.0328)^2 \times .7854 = .000845$ square feet.

By Table 9, coefficient of discharge due a head of 2.25 feet, according to Castel, is approximately equal to .673; then by Rule 27,

$.873 \times .0025 \times 1.5 \times .000845 \times .00685$ cubic feet.—Ans.

Cal. 2d.—According to Weisbach, the coefficient due a head of 2.25 feet, and orifice .0328 feet diameter, is approximately .628. Employing this coefficient instead of .673,

$.628 \times .0025 \times 1.5 \times .000845 = .00639$ cubic feet.—Ans.

Weisbach observes, that "for square orifices from 1 to 9 square inches area, with from 7 to 21 feet head of water, according to the experiments of Bossut and Michelotti, the mean coefficient of efflux is $m = .610$;

for circular ones of from $\frac{1}{2}$ to 6 inches diameter, with from $\frac{1}{4}$ to 21 feet head of water, $m = .615$."

A mean of the coefficients of Table 9 is equal to .62 nearly.

In ordinary practice this is employed. When greater accuracy is required, reference will need be had to Table 9.

PARTIAL CONTRACTION.

Experiments show that if contraction be suppressed, the flow of water through an orifice will be increased accordingly.

Let $n =$ the ratio between the entire perimeter of an orifice and the part suppressed—that is, if p denote the entire perimeter, and p' the part suppressed, then $n = \frac{p}{p'}$.

$c =$ coefficient of discharge due perfect contraction.

$c_n =$ coefficient of discharge due partial contraction.

$x =$ a number deduced from experiment, which, being multiplied by the product of the ratio, n , and the coefficient, c , gives $c_n x n$, the increase due partial contraction; thus,

$$c_n = c(1 + xn) \quad (93)$$

An inspection of Table 9 shows that the coefficient of flow for small orifices and for small velocities, is greater than it is for large orifices and for great velocities.

It will also be observed that the results of experiments differ considerably, though the data employed is approximately similar.

Thus Castel finds the coefficient of flow for an orifice .0328 feet diameter, under a head of 2.132 feet, to be .673; while Weisbach finds it, for an orifice .0328 feet diameter under a head of 2 feet, to be .628.

Bidone's experiments give, for circular orifices, $x = 0.128$, and for rectangular orifices, $x = 0.125$.

Weisbach's experiments give, for rectangular orifices, $x = 0.134$.

Weisbach, however, employs for rectangular orifices the mean between these results—that is,

$$1.5 \frac{.125 + .134}{2} = 0.143.$$

Substituting these values in eq. (93) there results, for circular orifices:

$$c_n = c(1 + 0.128n) \quad (94)$$

And for rectangular orifices:

$$c_n = c(1 + 0.143n) \quad (95)$$

TO FIND THE COEFFICIENT OF DISCHARGE OF PARTIAL CONTRACTION FOR CIRCULAR AND FOR RECTANGULAR ORIFICES.

Rule 28.—Case 1st.—The orifice being circular, add 1 to .128 times the ratio of the entire perimeter to the part suppressed, and multiply this sum by the coefficient of discharge of perfect contraction.

Case 2d.—The orifice being rectangular, add 1 to 0.143 times the ratio of the entire perimeter to the part suppressed, and multiply this sum by the coefficient of discharge of perfect contraction.

Town Sites and Mineral Lands.

The Supreme Court of the United States has made a decision of great importance in a conflict between the claimant of a placer claim and a town site in Dakota. The decision brings on the question of people occupying mineral land for other purposes than mining. In effect it decides that people cannot get a good title to land known as mineral, unless it is purchased for the purposes of mining. The decision is very long and interesting, and we shall shortly give it in full. For the present we give a syllabus as follows:

1. No title from the United States to land known at the time of sale to be valuable for its minerals of gold, silver, cinnabar or copper can be obtained under the pre-emption or homestead laws, or the town site laws, or in any other way than as prescribed by the laws especially authorizing the sale of such lands, except in the States of Michigan, Wisconsin, Minnesota, Missouri and Kansas.

2. A certificate of purchase of mineral land upon an entry of the same by a claimant at the local land office, if no adverse claim is filed with the Register and Receiver, and the entry is not cancelled or disaffirmed by the officers of the Land Department at Washington, passes the right of the Government to him, and, as against the acquisition of title by any other party, is equivalent to a patent. The land thereby ceases to be the subject of sale by the Government, which thereafter holds the legal title in trust for the holder of the certificate.

3. The officers of the Land Department have no authority to insert in a patent any other terms than those of conveyance, with recitals showing a compliance with the law, and the conditions which it prescribed. The patent of a placer mining claim carries with it the title to the surface included within the lines of the mining location, as well as to the land beneath the surface.

4. There can be no color of title in an occupant of land who does not hold under an instrument or proceeding, or law purporting to transfer the title or give the right of possession. Nor can good faith be affirmed of a party in holding adversely, where he knows he has no title, and that under the law, which he is presumed to know, he can acquire none. So held where, in an action of ejectment for known mineral land by a holder of a patent of the United States, and the occupant set up a claim to improvements made thereon under a statute of Dakota, which provides that "in an action for the recovery of real property, upon which permanent improvements have been made by a defendant, or those under whom he claims, holding under color of title, adversely to the claim of the plaintiff, in good faith, the value of such improvements must be allowed as a counter claim by such defendant," he not having taken any proceedings to acquire the title under the laws of Congress authorizing the sale of such lands, or to acquire the right of possession under the local customs or rules of miners of the district.

5. It would seem that there may be an entry of a town site, even though within its limits mineral lands are found, the entry and the patent being inoperative as to all lands known at the time to be valuable for its minerals, or discovered to be rich before their occupation and improvement for residences or business under the town site title.

ANNUAL EXPENDITURES.—Owners of unpatented mining claims have less than a month remaining, in which to do the annual holding work required by the mining act of Congress. All unpatented claims on which \$100 worth of work was not done before January 1st, were forfeited and subject to relocation, according to the old ruling of the Commissioner of Public Lands. A more recent ruling provides that in cases where owners or locators of mining claims are actually engaged in doing their annual work on January 1st, such claim is not subject to relocation, provided the owner puts in the full amount of labor required by law during said month.

NEW DISTRICT.—Some rich gold claims have been discovered about 15 miles east of Schurz station, a station on the Carson and Colorado railroad, Esmeralda county, Nev., and a new district has been formed under the name of Victoria mining district. The boundary lines are defined as follows: Commencing at a point three miles due north of the "Black Hawk" discovery shaft, thence three miles due west, thence due south six miles; thence due east ten miles, thence due north six miles, thence due west seven miles to point of commencement. Wm. G. Young has been elected Recorder for the district.

NOGALES, ARIZONA.—There will soon be a smelter at Nogales, Arizona, and Mr. C. H. Aaron, the assayer at that place, writes us that his business already feels the favorable effect of it. Mr. Aaron is well known from his works on assaying and metallurgy, and is in a location where he is enabled to attend to business in connection with mining, both in Arizona and Sonora.

The bill of exceptions in the case of A. D. January was stricken from the court records at Sacramento. The sentence of January is for ten years at Folsom.

USEFUL INFORMATION.

A Lesson in Shop Management.

The costly results of putting off till to-morrow the thing which ought to be done to-day are nowhere more surely felt than in a workshop. The number of unsuccessful shops or actual failures in business which could be traced to this habit can scarcely be told—but they are very numerous. How this evil was pointed out and checked in one workshop is related by the *Cabinet Maker* as follows:

"We once worked in a shop where a specialty was made of builders' finish, brackets, moldings, fancy finish, etc. About eight hands were employed in the room we worked in. The machinery consisted of railroad combination, band and jig saws, panel and buzz planer, a boring machine and a two-spindle molder. The two planers and the jig saw had loose pulleys, which were so badly worn as to necessitate throwing off the belts from the main shaft to the counter every time each machine was used. In that shop each man took an order from the order book, got out his stock and finished the job, using whichever machines were needed. When it was necessary to use the panel planer we had to climb up on the jig saw table and throw on the belt; when the buzz was needed, the planer must be used to stand on, in order to get at the requisite belt. If the planer was running it must be stopped, thus delaying the man who was running it.

One day after getting thoroughly disgusted we "went for" the boss and asked him if he was going to have those pulleys hushed this year. He said he was going to "just as soon as he got time," but he let them run in this way for two whole months. One day we noted the number of times we had to throw on and off those belts. We used the planer 15 times, the buzz 10 and the jig saw 16 times, making 41 times in all. It took about a minute to put on, and another to throw off a belt, thus making in all 80 minutes in one day. There were eight of us who had to do the same thing, so it took 650 minutes, or 11 hours, to handle those belts—more than one man's time every day. Running this way for nine weeks would amount, at the rate of 40 cents per hour, to \$212, and our boss could not find time to have the pulleys fixed. We showed the figures to him one day. He scratched his head, took them into his office, and ten minutes afterward came out, shut down the shop instantly and sent these counters and pulleys to the machine shop. A loose pulley that rattles has not been seen nor heard in that shop since. You may go in every shop in the land and six out of every ten will have one or more of these "hand shippers" in operation. How is it in your shop?—If the coat fits put it on."

Large or Small Engines—The Safe Side

The natural and commendable desire to be on the "safe side" in making a calculation may be, and often is, carried to an extreme which leads into a greater error than that which it is sought to avoid. A man is going to put in an engine; he has often heard and read of the wastefulness of too small a motor; and so, to be on the "safe side" he orders an engine which is correctly proportioned for about four times the load which it will be run under, reasoning that a big horse can drag a little load but a little horse cannot drag a big load. There is this difference between the horse and the engine: that while the big horse might not cost any more to buy or to keep, both the selling price and the cost of running an engine increases with its size, owing not only to the increased friction of the larger machine, but to the fact that in order to keep it from exerting its great power it must be run with low steam, a high grade of expansion, and at a very low speed. The owner finds in consequence, that he has paid a number of hundred dollars more than he needed for a machine which is less economical than the smaller and cheaper would have been, in order to be on the "safe side."

It is quite as possible, though not so frequent in occurrence, that the boiler power may be too great as it is too little, and as for the boiler material the government authorities are obliged, in the interests of safety, to restrict the fire sheets to a given thickness.

Many superintendents and managers will, to be on the "safe side," fit their boiler room up with all manner of patent traps and get it where it will almost run itself, or so that "anybody can run it," and then to be on the "safe side" of the ledger they put any "thing" in to run it. Any "thing" depends upon the safety automatic machinery to look out for everything—he does not even look after the machinery itself, and when it slips up at some critical moment with more or less damage, who is to blame? Any "thing," the automatic safety appliance, or the man who substituted it for brains, to be on the "safe side."

ANTIQUITY OF SHEEP ON THE EARTH.—It is a somewhat singular fact that no unequivocal fossil remains of the sheep, have yet been found in the bone-caves, the drift, or the more tranquil stratified newer pleiocene deposits, so associated with the fossil bones of oxen, wild boar, wolves, foxes, otters, heavers, etc., as to indicate the coevality of the sheep with those species, or in such an altered state as to indicate them to have been of equal an-

tiquity. Wherever the truly characteristic parts, viz., the bony cores of the horns, have been found associated with jaws, teeth and other parts of the skeleton of a ruminant, corresponding in size and other characters with those of the goat and sheep, in the formations of the newer pleiocene period, such supports of the horn have proved to be those of the goat. No fossil horn-core of a sheep has yet anywhere been discovered; and so far as this negative evidence goes, we may infer that the sheep is not, geologically, more ancient than man; that it is not a native of Europe, but has been introduced by the tribes who carried hither the forms of civilization in their migrations westward from Asia.

NEATNESS IN THE ENGINE ROOM.—In some engine-rooms that we know of, says an exchange, there are carpets down the center and a bright oilcloth close to the engine and all about it. There are even pictures on the walls, and plants in pots in the windows. The engine does not say a word. Beyond the signing of the exhaust and the "creep" of the main belt, as it parts from the pulley, there is not a sound to indicate that there is a tremendous force at work. Contrast this with the hammer and tongs, a clatter like bedlam broken loose, broken windows, and floors like an oil works for filth, and we have just the difference between thrift and sloth, between care and carelessness, between proper economy and the "willful waste" that sooner or later "makes woeful want."

BOILER INSURANCE.—In steam boiler engineering the only observable change seems to be the slow but steady gain made in the introduction of water-tube coil boilers, and in the extension of a rational system of inspection and test while in operation. To-day the intelligent owner of the boiler secures inspection and test with insurance, by intelligent engineers, and responsible underwriters as invariably as he obtains inspection and insurance of his buildings. Under this system, steam boiler design, construction and management is becoming a distinct art based upon real knowledge. The system of forced circulation proposed by Trowbridge and others seems to me likely to prove useful in the solution of the problem to-day presented.—*Thornton.*

EXPLOSIONS IN MINES.—A permanent commission has been appointed in Austria for investigating the causes of explosions in mines. Among the subjects to be dealt with are safety lamps, coal-dust explosions, meteorological observations, the employment of gunpowder for blasting, and ventilation of mines.

GOOD HEALTH.

Inoculation for Hydrophobia.

Another splendid triumph has been achieved by M. Pasteur in effecting a cure for one of the most terrible of human maladies—hydrophobia, which to all present appearances is to be stamped out of existence, wherever the remedy is applied.

It is now several years since this indefatigable worker has been directing a large portion of his time and skill to devising means for the cure of this dread disease, and we have now almost indubitable evidence of his complete success. His process is that of inoculation. Some time ago he succeeded in rendering proof against rabies some 16 out of every 20 dogs experimented upon. But to ascertain that immunity had really been given he had to wait four months after the inoculation had taken effect. He therefore set himself to obtain virus of different degrees of strength, with the object of obtaining prompter and more certain results. This was effected by the following means:

How the Virus is Obtained.

A rabbit was inoculated with a fragment of tissue taken from the spine of a rabid dog. The incubation of the poison occupied 15 days. As soon as the rabbit was dead, a portion of its spinal marrow was in turn inoculated into a second rabbit, and so on, until 60 rabbits had been inoculated. At each successive inoculation, the virus became of increased potency, and the last period was not more than seven days. Having ascertained that exposure to dried air diminishes the virus, and consequently reduces its force, M. Pasteur supplied himself with a series of bottles containing dried air. In these bottles were placed portions of the inoculated spinal marrow of successive dates, the oldest being the least virulent, and the latest the most so. For an operation, M. Pasteur begins by inoculating his subject with the oldest tissue and finishes by injecting a piece dating from two days only, whose period of incubation would not exceed one week. The subject is then found to be absolutely proof against the disease.

His First Human Subject

Was a man in the hospital, upon whom a perfect cure was obtained. His next patient was a young man from Alsace, who presented himself in July last, sixty hours after he had been bitten by a rabid dog fourteen times. His case, left to itself, being considered hopeless by M. Pasteur, Professor Vulpian and other high authorities, the patient was submitted to the same series of inoculations that had been so successful on dogs. As a proof, a series of rabbits

were simultaneously subjected to the identical processes. In 10 days 13 inoculations were made with pieces of spinal marrow containing virus of constantly increasing strength, the last being from the spine of a rabbit which had died only the day before. The youth thus operated upon by the successive administrations of weaker virus was made proof against the virus of the intensest strength. At the latest accounts, the young man was to all appearances perfectly well, while the rabbits, on the contrary, which were first inoculated with this strong virus, without first being rendered fit to receive it, became affected within the proper incubation period, and died with the usual symptoms.

The third patient is a shepherd boy whom Pasteur is confident of curing. The remedy having become publicly known, other patients are presenting themselves. This is certainly a brilliant discovery, and adds fresh laurels to those already won by the genius of M. Pasteur.

Six Cases from New York.

A few days ago six young boys were bitten by a mad dog in the State of New Jersey. Several medical and other philanthropic gentlemen immediately telegraphed the occurrence to M. Pasteur, at Paris, who readily promised to take their cases in hand if they were sent on by the next steamer. The money was raised and the boys sailed under the care of a matron—the mother of one of the little unfortunates—on the steamer several days ago. The result of the treatment of these American patients will be awaited with much interest and anxiety by the entire country.

BITTEN BY A CENTIPEDE.—A remarkable, and at the same time most distressing case of insect poisoning occurred in this city on Saturday last. In the afternoon of that day Miss Irene Tay, a well known society young lady, residing at No. 1005 Leavenworth street near Pine, was visiting a friend on the same street west of Davisadero. It was the season of housecleaning at the friend's house. The carpets were up, and while Miss Tay was walking through one of the rooms she felt something creep up one of her legs and bite her. The bite was followed by an insufferable burning sensation, and she decided to return home immediately. On leaving the car of the California-street line the young lady was obliged to walk about half a block to reach her home, and this she did with great difficulty, as her leg was paining her frightfully, and was partially paralyzed. On reaching her home and removing her clothing, by the assistance of her mother and sister, an enormous centipede fell to the floor. Members of the family applied arnica to the injured limb, but it afforded little relief. The member was much inflamed and swollen. A druggist was sent for, but he afforded little relief, and finally Dr. Eckle, the family physician, arrived. The doctor pronounced the case a very serious one. The young lady was suffering so severely that it was feared she would die, but under the care of the physician she recovered, so that now she is thought to be out of danger. The centipede was three and a-half inches long and supplied with innumerable legs and tentacles. An attempt was made to kill the venomous reptile by pouring ammonia on it and scorching it with a flat iron, but it seemed to suffer little inconvenience from these attentions. It was finally placed in a bottle and shown to the physician, who at once announced its dangerous character.—*Call, Dec. 5th.*

A RAPIDLY GROWING HEALTH EVIL.—It is not generally known that coal oil and gasoline stoves rapidly vitiate the air of a room for breathing purposes by the development of large quantities of carbonic dioxide. How much longer must this continue before manufacturers of such goods will obviate this new danger by inventing some form of hood and pipe for conveying this poisonous gas to the outside atmosphere? Volumes have been written concerning the ventilation of homes, and the injury that arises, especially to children and the infirm, from crowding too many people together in closed apartments, and now, with the introduction of oil and gasoline stoves in the household, a new difficulty presents itself which is not easily remedied in the endeavor to provide for health and comfort. These stoves are frequently found with several large burners in full blast, in small kitchens hardly large enough to contain air to supply the healthful requirements of one person.

A DANGEROUS DIET.—The Los Angeles *Herald*, of November 20th, says, "At nearly midnight last night word was brought to the Sheriff's office in this city that a man had been found in the lower part of San Fernando valley in an almost dying condition from having eaten the fruit of the cactus, or tunas. The mouth, tongue and throat were terribly swollen from the poison from the spines, which are as fine as hair and sharp as needles. They are harbed, too, and when once they have penetrated the flesh it is all but impossible to extract them. The Indians eat them, but they are skilled in removing the spines in the most careful manner."

DANGER FROM FIG TREE TWIGS.—The Santa Cruz *Surf* says: A few weeks ago a little child of Seth Blanchard's was playing with some broken twigs from a fig tree and got some of the sap which exuded therefrom in her eyes. Her eyes became badly inflamed and it is reported that for some time the child has been entirely unable to see.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

GOOD ROCK.—Amador *Sentinel*, Dec. 9: The Moore mine is said to be turning out some first-class rock. Matters at the Kennedy are moving along smoothly and the mine is being got in working shape as rapidly as possible. Doucet & Co. intend running a tunnel into a hill below Matt Hackney's place near Clinton, with the intention of tapping what is apparently an old river bed and is believed to be rich in gold bearing gravel.

Amador.

FRESH DISCOVERIES.—Amador *Dispatch*, Dec. 12: We are pleased to be able this week to report fresh discoveries of very rich ore in the Moore and Amador Queen mines. In fact all the mines along the gulch are looking very well and other good strikes are expected soon.

TOMBSTONE HOPEFUL.—*Epitaph*, Dec. 12: Since the news of the big strike in the Contention, below water level, was made public, a feeling of renewed confidence in the future of the camp is noticeable among all business men. It is conceded by every one that this strike settles affirmatively the question of the success of deep mining in Tombstone, and consequently its important bearing upon our future prosperity cannot be exaggerated. It assures for Tombstone renewed activity in all branches of business and departments of trade. While the beneficial effects of the strike will not be fully felt at once, there is good grounds for the belief that ultimately it will place this city foremost among the mining camps of the continent.

Butte.

RIVER MINING SCHEME.—Oroville *Mercury*, Dec. 12: Major McLaughlin has rebounded the Lewis mining claim situated in Feather river a few miles above Oroville for the sum of \$2500. The mine embraces 3200 feet of Feather river and has never been mined. There is not the least doubt about the great wealth of this strip of river. When Cape Claim just below it was opened years ago, over \$600,000 were taken out in a run of 42 days, and at Long's Bar in the same vicinity millions were taken out in early days, as 800 or 1000 miners worked for a long time, and no miner worked in those days for less than an ounce or so. The Major thinks there is no doubt but that this mine will be opened up next spring, and if so we may expect a boom in this vicinity. The idea is to build a dam in the river at the upper end of the mine, and flume there by drying the bed of the river the entire length of the mine. The river has sufficient fall to make fluming easy, and there is nothing more plausible than the scheme. If it is undertaken there will be one of the richest developments that has been known in California since the early days. Since the Cherokee Company commenced to prepare for drifting they have within easy reach one of the finest channels of gold-bearing gravel ever found in this State. The tunnel spoken of before in these columns, has tapped an old river channel, containing a solid bed of gravel, that is estimated to be 1000 feet wide. The gravel in the vicinity of this, which has been worked by the hydraulic process, has been rich, every foot of it, and now that they can get at this immense bed, without washing surplus earth, there is no telling how much gold they will take out. Superintendent Glass expects grand results from his drifting scheme.

Calaveras.

BONDED.—Mt. *Echo*, Dec. 9: The Lindsay mine has been bonded to Joseph Ranks, of Angels. This famous quartz mine was discovered about the year 1855, and a large amount of gold taken out the first year. Since then large sums have been extracted by different parties, and it is to-day one of the richest mines in this county.

El Dorado.

IMPROVEMENTS.—Georgetown *Gazette*, Dec. 11: The enterprising owners of the Rip Van Winkle mine on Slate Mountain have made a great many substantial improvements on and around their mine this summer. Everything runs like clock-work, and every man working about the mine and mill seems as happy as if he owned a share of the mine. It is reported that the late clean-up at the Slate Mountain mine was ahead of any yet made. Those acquainted with the mine feel confident that it is the best paying mine in El Dorado county.

Inyo.

THE DEFIANCE.—Inyo *Register*, Dec. 10: We are informed that this mine is showing up magnificently. The tunnel running south on the 184-foot level extends something over 100 feet through an ore body from three to five feet in width, the higher grade of which assays from \$187 to over \$350 per ton in silver and from 50 to 70 per cent lead. P. Reddy, Esq., who has stuck to this mine with such wonderful faith, is in Darwin looking after the mine, and is loading all the returning teams from Panamint with this high-grade ore for shipment to San Francisco. The lower grades will be reduced in the old furnace, and of that class there is now enough to keep it running several months. It will not, however, be started before spring. At present the mine employs ten men.

RILEY MILL.—Inyo *Independent*, Dec. 10: John C. Eddy and Dr. Stevenson have leased the Riley mill. The mill is located between Darwin and Panamint. There is estimated to be between six and eight hundred tons of tailings at the mill; the stuff assays \$22 a ton and the mill will be started up at once to work this over. In the mean time men have already been put to work doing assessment work in the mines, and if the prospect is such as will justify continuing the work it will be kept up.

LOOKOUT.—A few days ago Frank Fitzgerald finished a very successful run at the furnace at Lookout. The run was completed in six days and the value of the bullion is about \$12,000. The grade is higher than any run made at Lookout for some time.

Mono.

BENTON.—Cor. Inyo *Register*, Dec. 10: Mr. J. E. Miller has completed an underground and surface survey of the Borasca mine, and located a point for the sinking of a shaft to secure proper

ventilation for the mine, which continues to show the usual quantity of good ore in the stopes. He has also in view the running of a new tunnel on the ledge to connect with the upper workings. Judge Tucker has struck another fine body of rich ore in the Eastern Star, and is hard at work opening it up, with prospects improving. Pete and Henry McCabe are taking good ore out of the Laura on tribute from the Little Emily M. & Co. The company's mill at Montgomery is running steadily on the ore bought from Mr. McBride, which is paying well. At the south end Kremkow is drifting south on the Kearsarge, and as soon as sufficient timbers and lagging can be secured, intends to sink the shaft 100 feet deeper.

Mariposa.

DILTZ.—Mariposa *Gazette*, Dec. 12: Ore from the large dump on the north side of the hill, which has already been through the washing before piling, and \$14 a ton of free gold realized therefrom, assayed \$30 a ton. This proves that had the whole of the quartz and vein matter been put through a mill, it would have paid \$44 a ton. There is 600 tons of ore in this dump of a suitable fineness, or crushed, all ready to be put through a mill, besides some thousands of tons of the same character of rock in sight, which can be collected with remarkable facility and easily transported to a mill. Captain Diltz will no doubt erect a mill at this point early in the spring, providing he does not sell his mine, as at present is contemplated. Negotiations for the sale of the mine have been going on with several different parties during the past year, and it is highly probable some one of them will purchase the whole property ere another season passes.

Nevada.

WILL SOON START.—*Tidings*, Dec. 12: Arrangements are now about perfected for the immediate working and opening of the Coe mine. Robinson, the great circus manager, had bonded this mine, but recent disasters in the sinking of steamers and the wrecking of railroad trains has so altered Mr. Robinson's business that he cannot come here immediately to attend to the affairs of the mine. Mr. Geo. Murphy, A. D. West and Zeph Mansau have now taken the matter in hand, and it will be but a very short time before the mine will be in full blast.

PAY GRAVEL STRUCK.—*Transcript*, Dec. 12: This week the shaft in the Centennial drift claim, Washington township, struck bedrock in the long-sought channel at a depth of about 250 feet, and developed a fine body of pay gravel. The pumps now in use being of insufficient capacity to handle the large quantity of water coming in were removed shortly after the strike was made, and operations will not be resumed until spring when new and heavier machinery will be put in. The Centennial claim is owned by an incorporation, the stockholders in which principally reside at Gold Hill and Virginia City, Nevada. Prospecting was commenced there in 1875 or perhaps earlier under the superintendence of Major Downie, and has been prosecuted most of the time since then. Long tunnels have been run and shafts put down, the expenditures probably approximating \$75,000. The stockholders have put up assessment after assessment (the 22d one will be delinquent this month) with a promptness that evidenced their implicit faith in the eventual discovery of a rich mine. That their persistence and nerve are now in a fair way to be liberally rewarded is quite certain. The finding of the main channel and pay gravel by the Centennial Company will put new life into that part of the county and give an impetus to gravel mining along the rich and extensive channel that traverses the Centennial and neighboring locations.

THE MINERAL BELT.—Helena *Independent*, Dec. 10: Work on the two tunnels of the Mineral Belt Company is progressing fairly and with the utmost satisfaction to the contractors, superintendent and stockholders. This company is prosecuting work on two tunnels, one 300 feet below the mouth of the first one and 750 feet east of it. The lower tunnel just misses the ground claimed by the Regulator lode, passing by the west end of it within 100 feet. Both of these tunnels are now in over 100 feet, and are being driven at the rate of about four feet every 24 hours, three shifts being worked on each of them. These tunnels are being driven in clear ground, where there are no lodes located at present, but with known lodes close up to them on either side. The first 90 feet through volcanic shale, thrown down from the mountain through countless ages, but both are now in solid formation. It is predicted by the contractors that a lode will be cut in the upper tunnel within the next 25 feet, as the character of the rock now being taken out shows unmistakable signs of a lode being near.

PHOENIX MINE.—Grass Valley *Union*, Dec. 10: A crushing of 23 loads of rock from the Phoenix mine is being crushed at the Rocky Bar mill. It was mostly taken from the shaft, and therefore not all clean quartz, but nevertheless is expected to give a fair result. Recently a double stringer of quartz, being respectively six and eight inches in width, has been found in the north drift on the lower level, which prospects well in gold. The work of sinking the main shaft is going on steadily, and it is expected to turn a drift for a new level about the holidays, when rich rock is expected from the chute coming down from the level above, where fine specimens were taken out a few weeks ago. The prospects of the Phoenix are considered excellent, and the members of the company are all sanguine as to the future of the mine.

ANOTHER GOOD PROSPECT.—Some weeks ago John Trenberth, Wm. Thomas and others started work on a quartz ledge near the old Town Talk gravel mine, opposite George Wilson's ranch, and the outlook is now very encouraging. A shaft was sunk on the ledge, and at a depth of 25 or 30 feet it was found to be about six feet in width, and the rock looking well. The men could do no more work at the present time.

COMMENCED CRUSHING.—*Tidings*, Dec. 9: Teams have been busy for the past several days hauling ore from the Phoenix mine to the Rocky Bar mill, where it will be ground up and the gold taken from it. The rock is a likely looking lot, and will no doubt meet the expectations of its most ardent admirers. It will probably be some time next week before any definite idea of its value can be had.

ORLEANS MINE.—Grass Valley *Union*, Dec. 9: The shaft of the Orleans mine is now down within a few feet of 200 feet below the tunnel level, or 350 from the surface. The ledge in the shaft is small, but prospects in free gold. In a few days the drift will be turned in the direction where the ledge is believed to be much stronger, as shown in the level

above, and which was also of good paying quality. From the amount of water now coming into the shaft it is thought a strong vein is close at hand.

Plumas.

INDIAN VALLEY MINE.—Greenville *Bulletin*, Dec. 9: Work is progressing well. The drift from the bottom of the shaft is in 30 feet. The width of the ledge continues 22 feet, with smooth walls. The ore is of excellent quality and the entire width, as the drift progresses, is being extracted. A stope has been commenced near the face. The stope in the 100-foot level running west from the Indian Valley shaft, is looking well, furnishing its regular proportion of good pay ore. The drift extending toward the Union, will tap that mine 212 feet below its deepest works. It will take about six weeks to complete the task. The rock in this drift is very hard. The opening up of the Union mine to this depth is of very great importance, for when the ore from the deepest part was milled, it paid all the way from \$20 to \$40 per ton. It was a very rich chimney, and it is confidently believed that it will be equally as rich at greater depth. The body of ore thus made available in the Union will be large. In order that the extraction of ore may be more rapid, Mr. Cornell is arranging to put in Burleigh drills. They may be used in the various drifts, also in sinking the Indian Valley shaft. A number of experienced miners have arrived from below. The whole force for the present will embrace from 40 to 45 men. The probabilities are that when the mine is more fully developed, a much larger force will be employed.

Sierra.

CLEAN-UP.—The Bald Mountain Extension Co. cleaned up 167 ounces last week. The principal causes of the falling off from last week were that a flat place in the channel was encountered, and most of the gravel came from the rims in bringing those breasts up with the center workings. The Young America yield for a run of 27 days was between \$18,000 and \$19,000. While the yield was not as large as some had expected, it was large considering the quality of the rock crushed, which was low grade. It was a lot of rock that had to be got out of the way, and while it was known not to be exceedingly rich, it was also known that it was good milling rock, and would pay about \$18 per ton. The run, everything considered, was exceedingly satisfactory.

SIERRA CITY.—The Cleveland mine, situated in Nigger canyon, was started up on Monday for a short time. They are now hauling the rock on sleds, but intend soon to build a chute from the mine to the mill, which will greatly facilitate matters. The company has pushed the work with considerable energy, and it is to be hoped they will have their reward. The rock prospects well.

Siskiyou.

ORO FINO.—Yreka *Union*, Dec. 9: The recent rains have furnished an abundance of water for the mines in this vicinity. Scott river has been very high for the past week but is now subsiding and will soon be in its banks again.

Shasta.

NEW MILL.—Shasta Co. *Democrat*, Dec. 9: Bell & Co.'s new mill at French Gulch will soon be running. Last week Mr. Greer picked up a handsome \$17 nugget in Star gulch. Fred. Simonds, Sr. is up on Squaw creek prospecting. Several other prospecting parties are camped on Backbone. We are informed that a mining man by the name of Hart will erect a mill on Rev. Fleming's mines in Old Diggings district. The latter part of last week three carloads of Iron Mountain machinery were unloaded at Middle Creek and freighted to the mine. Inside of three years Squaw Creek will be the biggest and most productive mining camp in California. There are millions in it. Near Churntown Charles Jones and Vick Seams took \$100 out of a pocket ledge in two days, and are still extracting the "yaller" at the rate of \$20 per day. Reley, Mathews & Co. have got their road leading to their Squaw Creek mines about half completed. The company will endeavor to get their machinery in this winter. Bije Bemis is going to Copper City to assort the machinery he purchased for the custom mill in Old Diggings district. Such an enterprise is what all miners are interested in. Holt & Gregg have ceased operations at their lime quarry for the winter. An analysis of the lime rock shows it to be as pure as any found in the United States, and there is an unlimited quantity in sight. Mr. Carson, principal owner in the Snyder mine, has surely a most excellent showing for a rich mine on Squaw creek. He has just started a tunnel on the vein which will open up a rich body of ore. Prospects on the surface indicate a chimney of several hundred feet in length. Mr. Lindros and Davis, two prospectors recently from Oregon, last week made two valuable locations on Squaw creek. Their find is situated east of north of Whitton & Bassett's mines, and the ore shows up handsomely in free gold. Flunk Warner and John Lowden are interested in the property. Reid & Co. made a clean-up last week of about 50 tons of ore and obtained a result of 81 ounces free gold. The road being in such a bad condition sufficient wood could not be hauled in to keep the mill running and as a consequence work has been suspended for the present but will soon be resumed.

San Diego.

JULIAN DISTRICT.—Los Angeles *Express*, Dec. 14: Col. I. R. Dunkelberger said to an *Express* reporter to-day, "I have just returned from Julian. Fifteen years ago Julian had a big excitement. A reaction has set in. The first great strike was the Stonewall mine, which has plenty of high grade ore, and is running a ten-stamp mill day and night. The Ready Relief and the Redman mines jointly are running a ten-stamp mill day and night. They struck a large body of high grade ore in the Redman. The Hubbard is running a five-stamp mill with good results, and the Owens, leased some two months ago, sunk a perpendicular shaft, expecting to strike the ledge at 300 feet, but struck a ledge of which they knew nothing, at a depth of 100 feet and sunk on it 50 feet, and think they have ore enough on the dump to pay for the mine and their labor. The Shenandoah, Charlot and Ella have been bonded within the last two weeks, and the Hidden Treasure and Antelope have been leased for one year and work has already been commenced on the two latter. Other mines have been sold, among the number the Rowena and the Scott, on the Contact ledge, on which is the Chariot. The Rowena and the Scott I have bought and will work them. The ore is free milling gold. There are eight ounces of silver in the Rowena. The water is fine and the climate is per-

fect. Wood is abundant. The men who first discovered the mines had no capital. The Arizona excitement took them out there. Now capital is taking hold of these mines.

Sacramento.

GRAVEL.—Folsom *Telegraph*, Dec. 12: J. H. Bowman is developing a gravel claim near Robbers' Ravine, and is meeting with good success so far.

Trinity.

NEW RIVER.—Humboldt *Standard*, 12: Arrivals from New River bring the news that placer miners are at work, and that something is being done in the way of quartz mining and prospecting. An abundance of water is the great desideratum, and that the miners this season appear to have. There seems to be a cheerful outlook now in all the mines. Exchanges say the various mines at Deadwood are in a favorable condition; that the miners are contented with the prospect, and that great results in production and discovery are anticipated. The mining outlook in Trinity county is said never to have been better.

Tuolumne.

A STRIKE.—Tuolumne *Independent*, Dec. 12: A rich strike has been made in the old Melone lode belonging to the Carson Hill Company, at Robinson's Ferry. It was known that there was good rock left in the bottom of the shaft—some 300 or 400 feet deep—and lately a donkey engine has been pumping the water out. This was accomplished recently, and prospecting the shafts and drifts commenced. Last Sunday a rich spot was found, and on that day between four and five thousand dollars were taken out. Since then rich ore has been brought to the surface daily. The claim is on the mother lode right at the river. A company has been looking at Thos. Souby's mine at Arastaville, and he will doubtless make a sale of it. The mine is looking well and when further developed will become one of the leading mines of the county.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Enterprise, Dec. 12: On the 3000 level work is being actively prosecuted, upraising and stoping out in the ore body above the deep winze station. This upraise has extended upward about 30 feet, and will be continued to the 2900, stoping out the ore as it progresses. Hoisting the ore which has accumulated in making this opening was commenced day before yesterday, 70 tons being raised, and as much more was taken to the surface yesterday. This will be continued as opportunity offers, and milling will follow in due time. This ore is of a good grade which averages well under the stamps, and samples can easily be picked from the dump which will assay high in the hundreds. On the 3000 level in crosscut No. 3 they have commenced stoping out the ore body with a view to hoisting ore from that point also for milling. The diamond drill being run northeast from the face of the main north lateral drift brought out some rich black sulphur drillings, demonstrating the existence of a good ore body or vein in that direction.

CHOLLAR.—The main lateral drift south, following the west wall of the ledge, is now in 640 feet from the Combination west drift, and having reached the Potosi north line day before yesterday, it was stopped. A small stream or seepage of water was met with at this point, merely three or four inches, and now drain boxes are being put in the entire length of the drift to carry off this water and any more that may be met with in future operations. This will take a couple of weeks, after which it will be decided whether to continue the drift south into Potosi ground or to crosscut east in the fine large ledge developed and lying along the east side of this drift.

CON. CALIFORNIA AND VIRGINIA.—About 125 tons continues to be the regular daily yield from the 1750 level, assaying from battery samples at the Morgan mill \$15 per ton. The northwest drift on the 1650 level being run toward the old bonanza workings is now in 290 feet, having about 260 feet further to go. The Jones lease section, above the 1500 level, is yielding about 180 tons per day, assaying from battery samples at the Eureka mill, \$25 per ton. A large number of men are employed in the mine and the ore is being extracted at a very lively rate.

YELLOW JACKET.—The usual daily amount of about 175 tons continues to be extracted from the old workings above the 1300 level, keeping the Brunswick mill steadily running. The main lateral drift being run on the 1700 level from the Crown Point mine through the Kentuck makes good advancement and will soon reach the point at the north end where good redeveloements are expected to be made by it.

CROWN POINT.—About 360 tons is the regular daily yield, principally from the old upper workings above the 1400 level, with quite a contribution from the 1700 and 1750 levels, where the ore vein is not large but rather better in quality than from the upper levels. About 150 tons daily are being taken from the Belcher through the Crown Point shaft.

SIERRA NEVADA.—On the 520 level the main north lateral drift was extended 73 feet during the week, making a total distance of 1234 feet. Material in face soft vein porphyry, clay and quartz. A few tons of gold-bearing ore are being extracted from the surface croppings and shipped to the mill.

GOULD AND CURRY.—West crosscut No. 2, on the 1000 level, 170 feet south of the north line, is now in 245 feet, 37 feet having been added during the past week. Material in the face dry vein porphyry, with streaks of clay and decomposed quartz.

UNION CONSOLIDATED.—On the 500 level, the crosscut east, 100 feet south of the Sierra Nevada line is now in 335 feet, 28 having been made during the week. The vein matter in which it is running is of a very favorable and promising character.

KENTUCK.—This mine continues its regular yield of a little over 100 tons per day, supplying the Rock Point and Douglas mills. Everything goes right straight along like clockwork from one year's end to another.

OPHIR.—The main north drift on the 400 level, which has been running in low grade ore toward the Con. California and Virginia mine, has been stopped, and the west crosscut from it is progressing well toward the west wall in streaks and bunches of low grade ore. An east crosscut, started from the south drift, is now in about 60 feet, showing some small streaks of low grade ore.

Columbus District.

HOLMES.—*True Fissure*, Dec. 12: From the Cross development we are taking some good ore. At point 18 we are still driving the drift. The ground is a little softer and we are making better progress. The Creer drift looks better than at last report. The ore is fully 12 feet wide and is fine milling ore. It looks like it will prove to be a real bonanza. The fifth level crosscut has attained a total length of 120 feet, with no change in its general appearance.

MOUNT DIAHLO.—The east drift from the north crosscut on the fourth level is in 20 feet and the face shows 18 inches of \$40 ore. The east drift from the No. 6 winze is in 130 feet, and shows some low-grade ore. The raise from the east drift on the second level shows some \$40 ore. The intermediate, above the first level, shows a foot of \$100 ore.

Dun Glen District.

PLACER MINES.—*Silver State*, Dec. 11: Burrell Monroe says the Barber Canyon placer mines, near Dun Glen, are not turning out as well as anticipated. Water is encountered before the bedrock is reached, and the Chinese, who are working the mines, cannot control it. They have ordered pumps, and until they arrive they can accomplish but little, as the gold-bearing gravel is below the water line. Chinese have commenced prospecting in Auburn canyon, this side of the Dun Glen range, but with what success he had not ascertained.

Eureka District.

ACTIVE OPERATIONS.—*Eureka Sentinel*, Dec. 10: Considerable slag from the old K K furnace dump is being hauled to the Eureka Con. works. On Tuesday last two tons of ore were shipped in to the Richmond reduction works from the Summit mine on Prospect mountain. The Kesene mine, in Silverado canyon, keeps up its lick, and from it 18½ tons of good ore were shipped to the Eureka Con. furnaces the past week. Three tons of ore were shipped during the first part of the week from the El Dorado mine No. 2, on the west side of Prospect mountain, to the Richmond works. From the Tacoma mine, on Prospect mountain, one of the Ruby-Dunderberg properties, six tons of good ore were shipped to the Richmond works on Tuesday last. The Continental mine, on White Pine mountain is again among the ore producers, and from it 2½ tons were shipped to the Richmond furnaces the other day. The present competition between our local smelting companies should spur up our prospectors and induce them to push developments and send in their ore before winter sets in. The Lord Byron mine, one of the old stand-bys of Prospect mountain, continues to yield well. During the past week 5½ tons of ore were shipped to the Eureka Con. works. The present fair weather is putting the roads in good condition again. Those miners having ore to ship to the reduction works in town would do well to make their shipments at once. A shipment of ore lately made from the Water Jacket mine, Page canyon, to the Richmond furnaces, gave an average assay value of \$191.12½ per ton, two-thirds of the entire lot assaying over \$350 per ton. Charley Ruden and James Berryman, Jr., are driving ahead the tunnel of the Contention mine, Page canyon, Secret Canyon district. There is a nice lot of ore on the dump at the mine, ready for shipment. The tributaries in the California mine are doing good work and are proving that property to be just what has already been thought—that it is a banger. From it 47 tons of ore were shipped to the Richmond works the past week. The Adams Hill mines are looking and producing well. During the week ending yesterday, shipments of ore were made from that section to the Richmond works as follows: Mimbres mine, 3 tons; King Lear, 6; Oriental and Belmont, 16, and Silver Lick, 66. But little of the ore assays less than \$100 a ton, and it runs high in gold. The recent development in the Geddes and Bertrand mine, Secret Canyon, is looking well, and from it 14 tons of ore were shipped to the Richmond reduction works during the past week. There are seven or eight men at present at work in the property on day's pay. Messrs. Nelson and Anderson are still working on tribute and making very good wages.

Hawthorne District.

THE LAPANTA.—*Cor. Candalaria True Fissure*, Dec. 12: After examining the several prospect holes, tunnels, inclines and drifts, I have come to the conclusion that the theories advanced of the formation of veins, the kind of country rock and the particular direction, dip, etc., which are necessary to insure a true, good and paying lode have been exploded by the discovery of the Lapanta, and that few visitors can realize the immensity of this ore deposit and its value. Everywhere you go or look the ore is to be seen, and in the deepest workings the ore is the richest. It is hardly necessary to speak of the value of the ore. The company have had several hundred tons of ore crushed that is said to have yielded \$80 per ton and upwards. The ore is free, simple and easy to reduce, and is now being worked at the reduction works of Joshua Moss, at Kincaid. It is said by those who know that this concentrator renders the tailings of this rich ore absolutely worthless. The working of the mine is conducted by Billy Baker in a practical common sense method. Instead of sinking a three-compartment shaft somewhere in the vicinity of the ledge and drifting to find it, he has begun where it makes its appearance on the surface and followed it down in its serpentine course, never losing sight of it in the entire depth. No stopping of any consequence has been done, but the ore is being left in the mine until they can have greater facilities for reduction. Without asking any questions one would suppose they were doing this work with a view of the most practical mode of working the mine in the future and to the best advantage. There are numerous other rich mines in the district. The Red Bank mine is spoken of by many as the coming mine. The location is said to be one of the most favorable in Hawthorne district, and, excepting the Lapanta, produces the richest ore in the district.

Jungo District.

LOTTERY.—*Silver State*, Dec. 10: An assay of ore from the Lottery mine, in Jungo district, made in Virginia City, gave a return of \$235.57 to the ton. The Lottery is the property of W. C. Owens, McMillan, Richard Nagle and Geo. Rose. This assay was from their second-class grade of ore, some of the higher grade assaying at a very high figure.

Ophir Canyon District.

MILL.—*Belmont Courier*, Dec. 9: It is expected that the Ophir canyon mill will soon be started up

on ore from the Twin River Co.'s mine. Then look out for lively times in Ophir canyon.

Philadelphia District.

ORE.—*Belmont Courier*, Dec. 9: John Delabar is taking some very nice looking ore out of his mine in Arizona Hill. It is within the range of possibilities that he opens the largest ore body ever discovered in Philadelphia district; and he will do so to a certainty, if powder and muscle count for anything.

Park Canyon District.

NEARLY DONE.—*Belmont Courier*, Dec. 9: The Giant mill in Park Canyon is fast nearing completion, and soon the merry music of the stamps will be heard. We hope the bullion shipments will come up to the fondest expectations of the enterprising owners.

Tuscarora District.

ARGENTA.—*Times-Review*, Dec. 11: The drift on the 400 level has been extended 10 feet during the past week.

NORTH BELLE ISLE.—Fair progress has been made with the work on the 150-foot level.

GRAND PRIZE.—North drift on the 300 level has been extended 22 feet during the week, and raise above the 300 has been connected with the 200, so the ventilation is good now.

NAVAJO.—No. 1 crosscut west, 350-foot level, extended 40 feet. No. 2 crosscut, 250-foot level, extended 11 feet. West crosscut from east lateral vein, same level, extended 7 feet.

MEXICAN.—On the 300 level the lateral drift north from the east crosscut is in 173 feet, and the south lateral drift opposite to it 187 feet. Both continue in promising vein matter.

ALTA.—Some good bunches and streaks of ore continue to be met with in the explorations on the 700 level, near the upraise from the 950 level.

ARIZONA.

MORE ORE.—*Prescott Courier*, Dec. 9: Wm. Jennings, an industrious miner, has just shipped 200 sacks of ore to Pueblo. He has several good mines in Hassayampa district. A considerable addition to the present force on the Sterling mine has been engaged. Several of the men leave here this morning for the mine. The flume, dam, etc., of the Oro Fino hydraulic works are pretty nearly completed, and the quality of the placers will be practically tested by the close of the year. It is asserted by the Phoenix papers, that Messrs. Cook, Church and Gray, of this city, have purchased the Tip Top hoisting works and the Gilette mill, and will remove them to their mines near Tule lake.

BULLION AND BULLION PRODUCERS.—*Prescott Courier*: D. Levy & Co., merchants of this place, shipped, yesterday, to Pueblo, Colorado, about three tons of gold-bearing rock for Mr. Hall, of Hassayampa district; also a lot of silver ore for Lawler Bros. It is expected that the gold rock will yield over \$150 to the ton. The silver ore is also very rich. A pack train laden with silver ore, from the Blue Dick mine, arrived in Prescott yesterday. Mrs. Hughes has discovered what is thought to be a good silver ledge, near the Aztlan mill, Groom Creek district. Dr. Farnham is taking rich rock from the Ironclad mine, Walker district, and is preparing to run it through his steam arrastras. Owners of placer mines are piling up auriferous gravel, so as to be prepared to wash the gold out of it as soon as water comes. A great deal of assessment work is being done in almost every district of the county.

MOHAVE.—*Miner*, Dec. 13: Mr. Shaw has four men working on the Antelope mine at Wallapai mountain. They are running a tunnel to tap the main shaft, and when this is done we may look for large shipments of ore from this mine, which is one of the best in the district. There are about twenty-five men working in the Lost Basin. Stevens & Co.'s new mill is expected to be running in about two weeks. There are four men at work on the American Flag mine, at Wallapai mountain, and from all reports the owners of this valuable property are making money rapidly. W. H. Hardy has three men at work on the infallible mine at Stockton Hill. John K. Mackenzie has struck another good body of ore in the north drift of the Cupel mine.

COLORADO.

REPUBLICAN MOUNTAIN.—*Georgetown Courier*, Dec. 10: A *Courier* representative visited the property of the Republican Mountain Silver Mines Company last Friday, and was surprised at the immensity of the mine and the amount of rich ore exposed. The property is located on Republican mountain, within one mile of Georgetown, and consists of the Everett, Morning Star, South America, Fenian and eight other claims, embracing 10,000 linear feet of veins covered by patents. The location is superb, for unlike many other mines situated so far from ore markets that the expense of transportation greatly lessens the profits or prohibits the working of lodes, or where the snow-fall is so great as to impede or prevent mining during several months of the year, these mines are near the ore markets and transportation charges are small. The Everett tunnel has been driven 800 feet for the development of the property. At 450 feet the Morning Star vein is intersected at a depth of 250 feet from the surface. Over 300 fathoms of ground have been stope out above the east level, and the work of extracting mineral still goes on. The workings are all substantially timbered under the personal supervision of B. C. Catren, and are planned in a manner that renders the work of developing the property systematic and economical. The mine is self-drained, and rock from the upper workings is dumped down the shaft to the tunnel level and trammed to the dump. Some excellent ore bodies are to be seen, and although the work being done is confined almost entirely to development, sufficient ore has been extracted to defray all expenses for the past six months. At present a force of 35 men is employed, with a monthly payroll of over \$3000. The character of the mineral is galena, gray copper and a little native silver, and occurs in veins ranging from one to ten inches wide. The ore mills from 100 to 600 ozs. in silver to the ton and an average of 20 per cent in lead. It is estimated that over 8000 fathoms of ground are opened ready for stopeing, and the amount is being increased daily. In addition to the lodes mentioned, the company owns a valuable mill-site and water power near the mouth of the tunnel upon which a force of men is at present employed in excavating for and laying the

foundation of a mill which the company contemplates erecting this winter, for crushing, sampling and concentrating ores.

IDAHO.

KETCHUM NOTES.—*Keystone*, Dec. 7: The deep tunnel at the Senate mine, Galena, is still being pushed ahead. Hunt's placer claim at Salmon Falls is yielding steadily from \$500 to \$600 per month. A force of six men was put to work on the Japan mine, on Carbonate Hill, under the foremanship of Captain Ritchie. The Vienna Mining & Milling Co. has reduced its force to fifty hands. The prospects are favorable for an all winter's run. The Morison Group of mines at Bullion, including the Nellie, Sim, Vanderbilt, Belle of the West, Mormon Girl and Homestake, have been leased for eight months to Billy Welsh and Thos. Winsted. Pinkham & Lewis' interest in the Carrie Leonard mine, on Little Smoky, was sold on Tuesday, the 1st instant, to Wm. H. Watt and J. O. Swift of Hailey for \$6,500 cash down. The Carrie Leonard has been a dividend-paying mine all season and is at present a fine looking property. The price paid is thought to be low. M. Carrey, lessee of the Tenbroke, shipped to the smelters last week the finest lot of ore that ever came from the hills of Warm Springs Creek. It was nine tons, running 75½ per cent lead and 158 ounces per ton in silver. This is really beyond the custom of that little mine, but quite consistent with Mr. Carrey's usual good fortune. The Irving under his management is looking excellent—a twenty-inch vein of good ore having been struck last week. This mine will probably make the next shipment.

STRUCK IT RICH.—*Idaho World*, Dec. 9: The Silver Chief boys are jubilant over the strike in the air crosscut, some 20 feet north, and a little to the west of the main shaft, at a depth of 72 feet from the surface and 200 feet west of the Banner mine. The character of the ore is similar to that of the Banner, being ruby, native, horn, brittle and antimonial silver. The vein at this point is 10 inches in width, and the ore easy to extract, the hanging wall being quite soft while the foot wall is solid porphyry, which is one of the best formations known for silver. Samples of the rock were assayed by the Elmira Company's assayer, Mr. Preswick, and the result was as follows: No. 1 sample, \$151.26; No. 2, \$49.77; average, \$100. This is considered extra good for this depth. The mine is well supplied with timbers, lumber and provisions to run until next June, by which time a large amount of rich ore will be hoisted to the surface.

MONTANA.

GOLD FIELDS.—*Inter-Mountain*, Dec. 9: A private letter received Sunday from a gentleman for whose word we can vouch, says: "The statement that Billy Edwards and others took out \$30 a day to the man for the past week is true. The claims have paid good wages all summer, but it is only recently that the boys struck it rich. I have a claim there that may prove valuable, but do not allow myself to dream of millions, for as a general thing, a miner's dreams of wealth dissolve in thin air, and he suddenly awakens to find himself confronting the cold question of 'grub.' But it is safe to say that a discovery of great importance has been made that will add many thousands to the wealth of the territory. The benefits derived will be perceptibly felt through out this entire section of the territory. A number of promising leads have been discovered. Prominent among them is the Fair View, which has been developed to some extent. One or two lots were tested at the reduction works and paid a profit over cost of mining, milling and freight charges, but as the owners were well-to-do ranchmen, they were content to patent their claims and wait more favorable conditions for development work than have yet existed. Looking at the matter from the most conservative standpoint, I think it safe to say that the new diggings will pay well, and as a result we will have many bonanza quartz leads added to those already in the territory."

LARGE MINING SALE.—*Helena Independent*, Dec. 11: For some time past negotiations have been pending in regard to the purchase of the Alpha and Omega mines, situated in Stemple District, about 35 miles north of Helena. These mines are located on a high ridge trending east from the main range, and are an extension of the well-known and valuable property known as the Homestake mine. The country rock is slate, and the vein matter is a soft quartz material, carrying a high percentage of gold. The mines are easily worked, requiring very little, if any, blasting, and will no doubt prove valuable when proper facilities for treating the ore are at hand. The Homestake, which is on the same vein, and has the same characteristics, has produced \$10,000 a month for the last seven months with a five-stamp mill, and the tailings run as high as \$30 in gold. Adjoining the Omega mine on the west is the Badger, which has been developed but little. Then comes the Bachelor, a fine property, which joins the Homestake. The Bachelor is developed by a tunnel over 300 feet long, which taps the lead at a depth of 200 feet, showing a good vein of rich ore. The Alpha mine has a tunnel run in at right angles with the lead, 335 feet in length. The perpendicular depth is 150 feet. The vein is small but rich. The country is well timbered, and at the base of the hill on the north runs Virginia creek, affording all the milling facilities that may be required. It is proposed to erect a mill on the ground at once, and prosecute the work of the mine.

NEW MEXICO.

WORK ON THE MINES.—*Socorro Bulletin*, Dec. 6: The Specie mine, owned by Chas. Blanchard, is now the scene of activity, and dumping good grade dry ore. Mike Wallace, last Monday, leased his Iron and George Belle claims in Water canyon to the Graphic Mining and Smelting Co., of this city. Mr. Kone-man, on Tuesday, dispatched a full quota of mineral to his Water canyon mines, with all necessary material, in charge of Mr. Douglas Brown. Bumbaugh & Peterson are working their Carbonate Queen in the Socorro district, and have up this date accomplished 400 feet of tunneling and shaft work, and will continue operations. We hear that Capt. H. M. Day, the well known Black Range miner, who is now in the city, will take charge of the Reserve mine in the Socorro district, and superintend the continuation of the work on that property. He will go some

200 feet further into the mountain. The Sheffield mine, in the Socorro district is dumping an excellent grade of silver chloride ore. The Graphic M. and S. Co., of this city, shipped 90 tons of bullion during the month of November last. The plant is running smoothly, principally on Graphic ore, and has run without interruption since it blew in. The two stacks are in full blast. R. N. Graham this week purchased of W. F. Eichbaum, of Albuquerque, one-half interest in the Modoc, La Luna and La Luna Fraction. These properties are in the Pueblo district, and make a good showing of mineral. The Brittenstene M. and M. Co. made a clean-up at their plant, in the Pueblo district last week, and ran out three gold and silver bricks, which have been expressed to the mint. The hopper of the Merritt stamp mill in Socorro is full of ore, and an immense body of it surmounts the hopper. Teams continue every day to augment this pile of silver ore.

UTAH.

REVIEW.—*Salt Lake Tribune*, Dec. 11: The output of the Ontario for the week was \$14,166.87, making its total yield for this year to date, \$1,521,112.18, out of which twelve dividends of \$75,000 each have been paid, and the thirteenth will come at the end of this month. The Stormont sent up three bars of silver on the 17th, from the Sandstone district, valued at \$4,300. The Horn Silver is reported as showing signs of renewed life, employing more men and apparently getting ready for something better than the restricted and non-productive operations of the past ten months. The Hanauer smelter turned out five cars of bullion during the week, valued at \$15,650; the Germania, five cars, \$11,693.20. Alice bullion, eighteen bars, valued at \$18,327.13, was received during the week. Ore receipts were—of miscellaneous, \$26,436.25; Queen of the Hills, Idaho, \$2,500; Sprucemont, \$4,100; Crescent, \$3,300; Milkmaid, \$241.95.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco.

NYE MINING CO.—Dec. 12. Location Nye Co., Nev. Capital stock \$500,000 in 100,000 shares. Directors, J. M. English, M. C. Fisher, Wm. J. Donlon, and Wm. D. Johnson.

ANGELS' QUARTZ MINING CO.—Dec. 12. Location, Calaveras Co. Cal., Capital stock \$100,000, in 1,000 shares. Directors, James V. Coleman, C. W. Tozer, H. C. McPike, Sands W. Forman and T. J. Schuyler.

BANKERS AND MERCHANTS' MUTUAL LIFE ASSOCIATION.—Dec. 10. Object: To equalize the risk of death and to pay to the nominees of such members as may die, stipulated sums of money. The corporation has no capital stock. Directors are: Alexander Badlam, W. H. Brown, Thomas R. Hayes, I. B. Thurman, R. W. Murphy.

HOSPITAL FOR CHILDREN AND TRAINING SCHOOL FOR NURSES.—Dec. 9. There is no capital stock; the institution not being organized for profit. Directors are: Irving M. Scott, Andrew S. Hallidie, Pierre B. Cornwall, John F. Merrill and W. Frank Whittier.

BUSH STREET RAILWAY CO.—Dec. 9. Object: Running and operating by wire cables or locomotive engines a railroad commencing at the intersection of Seventh and Channel streets, along Seventh to Market, across Market to the intersection of McAllister and Jones, along Jones to a point northerly to the property under control of the State of California; and also commencing at the intersection of Market and Bush streets, along Bush to Central avenue, along Central avenue to Sacramento, to First avenue, to D, to the ocean beach. Capital stock \$1,000,000 in 10,000 shares. Directors, Abner Doble, William Center, William Hanson, John S. Wright and Adam Grant.

Mining Share Market.

Hale & Norcross has enlivened the market a little, but whether the cause is due to supposed developments, or merely a stock deal, it is hard to say. The *Enterprise* says, however, that it is a fact that the diamond drill did bring forth rich borings indicating a good ore vein or deposit to the northeast from the face of the main north lateral drift on the 3100 level, and the upraising in the ore body above the 3000 level has developed a deposit of ore which assays high and from which a considerable quantity is being raised to the surface for milling. The workings at this point will be extended up to the 2900 level, extracting and milling the ore as the work proceeds. The main south lateral drift in Chollar, on the 3100 level, has reached the Potosi north line, and stopped in order to put in drain boxes the whole length of the drift to carry off what little water has been met with and any further supply that may be encountered. This will take a couple of weeks, after which future operations, whether to continue on into or through the Potosi, or to crosscut east in Chollar, will be decided upon. The usual progress of exploration and development is being made in all the principal working mines.

Bullion Shipments.

Argus, Dec. 12, \$534; Monitor, 5, \$25,570; Richmond Con. 10, \$15,813; Oro Grande Mill, 12, \$3775; Odessa Mill, 12, \$4100; Koebig Bros. Mill, 12, \$1000; Germania, 8, \$2414; Hanauer, 8, \$12,900; Sprucemont, 8, \$4100; Stormont, 8, \$4300; Queen of the Hills, 8, \$1200; Germania, 9, \$2559; Hanauer, 10, \$2750; Crescent, 10, \$3300; Alice, 7, \$8389; Alice, 8, \$6232; Hanauer, 11, \$4940; Nevada, 11, \$2200; Queen of the Hills, 11, \$1100; Alice, 11, \$11,990; Hanauer, 12, \$2500; Germania, 12, \$5662; Hanauer, 13, \$7560; Germania, 13, \$2730; Crescent, 13, \$4200. Following were the ore and bullion shipments from San Lake city for the week ending Dec. 12th. Twenty-one cars of bullion, 521,133 pounds, 18 cars of ore, 529,490 pounds, and two cars of copper ore, 71,350 pounds.

TATUM & BOWEN,

25, 27, 29 and 31 MAIN STREET, SAN FRANCISCO.

91 and 93 FRONT ST., PORTLAND, OREGON.

Manufacturers of

MINING MACHINERY, ENGINES, BOILERS, Etc.

We are manufacturing from Special Designs of the most experienced and successful Practical and Scientific Experts, Complete Plants for all descriptions of Mining Operations, as follows:

CONCENTRATING MACHINERY—Best and Cheapest, Cornish Rolls, all Steel Wearing Parts, Most Practical Styles of Two, Three and Four Compartment Double and Single Jigs, Sizing Screens, Patent Hydraulic Separators, Tables and Concentrators.

STAMP MILLS for Reduction of Gold and Silver Ores, whether free milling or base. Most useful and substantial styles of Single and Double Discharge Mortars, Wet or Dry Crushing.

STEEL SHOES AND DIES, Tappets and Cams, cheapest and best Blake Improved Rock Crushers and Automatic Ore Feeders, Superior Amalgamating Pans with wood or iron sides.

PANS FOR TREATING GOLD ONLY, Settlers, Clean-Up Pans, Retorts, Furnaces, Dump Cars, Hoisting Machinery, Cages, Landing Dogs, etc.

CORLISS, MEYER'S CUT-OFF AND BALL'S PATENT VALVE Engines of extra strength and durability.

STEEL BOILERS of Two Sheets only, Steel Economic Boilers, combining with the safety, durability and economy of the Stationary Boiler, the convenience and portability of the Portable. It occupies but little space, and is the best and cheapest boiler ever made.

WE ALSO MANUFACTURE SAW MILL MACHINERY.

We are also Sole Agents for the Gordon and Maxwell Steam Pumping Machinery, and carry a full stock of all kinds of Mill Supplies, including the

Albany Lubricating Compound and Oils.

1850. 1885.
RANKIN, BRAYTON & CO.,
...BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnaces CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER of INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ore.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY of CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000 pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

Centrifugal Roller Quartz Mill.

F. A. HUNTINGTON, MANUFACTURER OF

Centrifugal Roller Quartz Mills, CONCENTRATORS AND ORE CRUSHERS,

Mining Machinery of Every Description,
Steam Engines and Shingle Machines.

THE RISDON IRON AND LOCOMOTIVE WORKS.

Location of Works: S. E. Corner Beale and Howard Streets, San Francisco, Cal.

BUILDERS OF

QUARTZ MILLS—Gold and Silver, Copper and Lead Smelting Works, Roasting Furnaces of all kinds.
AIR COMPRESSORS—Rope Power Transmission.
HYDRAULIC PUMPING and Hoisting Machinery.
WROUGHT-IRON WATER PIPE a Specialty. Note:—Have just completed order for 35 miles of 44-inch pipe of 1-inch iron for Spring Valley Water Works Company, San Francisco.
SAW-MILL MACHINERY of all kinds.
STEAM ENGINES—Corliss, Slide-Valve, Poppet Valve, Automatic, Single, and Compound.
SOLE MANUFACTURERS for Pacific Coast of the Celebrated "Heine" Patent Safety Boiler (Water Tube); 50,000 horse power now in use.
MACHETH PATENT STEEL-RIM PULLEYS—Fifty per cent lighter and 25 per cent cheaper than cast-iron pulleys; will not break in transportation.

REFRIGERATING MACHINERY for Steamships, Breweries, and Cellars.
WILSON'S PATENT GAS-PRODUCER.
STEAM BOILERS of all descriptions.
SUGAR MACHINERY—Sugar Mills, Vacuum Pans, Clarifiers, Double Effects, etc.
STEAMSHIPS—Steam Yachts, Marine Engines and BOLLERS, Screw Propellers, Centrifugal Pumps, Steamship Pumps, Steam Capstans, Cargo Winches, etc.

Builders of 120-stamp Gold Mill for the Alaska Mill and Mining Company; 60-stamp Mill for Quartz Mountain Mining Company.

PATENT

LIFE-SAVING RESPIRATOR

Entirely Prevents Lead Poisoning and Salivation

The most perfect appliance for people engaged in Smelting, Dry Crushing, Guano Works, Quicksilver Mines, Lead Corroding, and all other occupations where there is dust, poisonous vapor, or bad odor.

In Feeding Threshing Machines, and similar work, they are indispensable, as no foreign substances can be inhaled when they are worn.

The Respirators are sold subject to approval after trial, and if not satisfactory the price will be refunded. Price, \$3.00 each or \$30.00 per dozen. Sent post-paid to any address on receipt of price.

A New Traction Motor.

The Automatic Traction Motor, recently invented by Edward Foskett, is based on the principle of utilizing the power of black powder.

We thus gain high power, rapid motion, quick application, with little weight, compact compass, and widespread distribution of fuel—all being essential elements of a good machine and its use.

The control of our fuel, the power from which we draw our force and store it, to use as required, is gained by a simple combination of plain mechanics. The power is started, increased, slackened, or stopped, by a brake.

The uses in the industrial field are limited only by amount of ingenuity applied.

As a highway motor, the model promises all that the "Puffing Billy" or the "Comet" did in locomotive growth. Recognizing its weight, strength and rapidity, it makes a strong appeal to solve the problem of aerial and circumpolar navigation, including numerous intermediate fields of usefulness, such as propulsion of street cars, etc. By this device, the snappish dictator of uncertain warlike conflict has become the glad protector of peace and the relief of labor. The unerring hand of inventive genius has thus stamped another epoch in progress.

Steam has a pressure of 200 pounds to the square inch; powder, over 60,000 pounds. Time and force are prime factors in overcoming resistance; as force is superabundant, time is decreased and vice versa.

We wish to investigate this force of nature now lying in the palm of enterprise, and develop a traction engine. We ask investigation, and invite capital to lend its assistance and share the rewards of a great improvement.

Those desirous of further information please call on, or address, D. N. DILLA, Adeline, near 34th Street, Oakland, Cal.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

BEST SOFT LAKE SUPERIOR COPPER USED.

Old Mining Plates Bought, Replated, or Gold Separated. 3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.

E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake. The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the
world. Unlike all other Packings, the Jenkins Standard
Packing can be made any thickness desired in a joint by
placing two or as many thicknesses together as desired, and
following up joint, it vulcanizes in place and becomes a
metal of itself (it is frequently called Jenkins Metal), and
will last for years, as it does not rot or burn out. Avoid all
imitations, as a good article is always subject to cheap imi-
tations. The genuine has stamped on every sheet "Jen-
kins Standard Packing," and is for sale by the Trade
generally.

Manufactured only by

Elevator, 12 Front St.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 220 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

\$1,000 CHALLENGE ACCEPTED.

PRICE, FIVE HUNDRED AND FIFTY DOLLARS
(\$550.00), F. O. B.

**THE
"TRIUMPH" ORE CONCENTRATOR.**

THE "TRIUMPH" TRIUMPHANT!

In a competitive trial recently had between two of the "Triumph" Ore Concentrators and the same number of "Frue" Vanning Machines, at the mill of the celebrated gold producing Original Empire Mill and Mining Company, in Grass Valley, Nevada County, Cal., the "Triumphs" produced thirteen and fifteen one-hundredths (13.15) per cent more concentrations than did the "Frue" Vanners, during a run of twenty-four consecutive days, or a net gold coin result of \$199.15, or \$8.30 per day, in favor of the two "Triumph" Concentrators.

These returns do not include the value of the amalgam saved by the "Triumphs" during the test; which will add to the net gain. The form of construction of the feed bowl is such that considerable amalgam is necessarily saved, which is lost on the "Frue" Vanners.

This trial was conducted under the personal supervision of the Manager and Superintendent of that Company, in a strictly fair and impartial manner, and with the sole view of determining, in the interest of that Company, the merits and demerits of the respective machines by a thoroughly practical test. A relation of the course of procedure, a concise analysis of assays, and a tabulated statement of the net hullion results, with accurate deductions therefrom, will soon be published in Circular form.

The superiority of the present construction of the "Triumph" over the form originally introduced, together with the demonstrated results of the above, and other trials had with the "Frue" Vanners, induce us to and we hereby accept the Challenge of \$1,000, flaunted by the Agents of the "Frue Vanning Machine Company," and hold ourselves in readiness to enter into a second competitive trial for that sum, at such place and upon such terms and conditions as may hereafter be mutually arranged.

We guarantee purchasers against all costs, expenses or charges incurred by reason of any infringements of any existing patents.

"Put up or shut up," and "Let the Best Machine win!"

Dewey & Co.'s Scientific Press Patent Agency { ESTABLISHED 1860.

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enabled us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

Shipments of Gold.

Very heavy shipments of gold are now being made from New York to Europe. It is stated that the most direct cause of this is to be found in the extremely light shipment of grain to Europe, especially wheat, while the visible supply of wheat in this country is far in excess of previous years. Merchants who are familiar with the subject also say that a considerable quantity of cotton was sold last July by planters, deliverable in 90 days, and that when the delivery way made there was a considerable advance in the price of spot cotton, which gave dissatisfaction to planters, and led them to hold the stock on hand for higher prices. United States Treasurer Jordao in giving his opinion on the subject, said that the reason gold was going abroad was that American exports were much lighter at this season of the year. Gold is now on a shipping basis, when the rate of exchange is at its lowest. This is due to the unusually light exports. And again, foreign holders of American securities

may be realizing, and that would take a good deal of gold from our shores. These foreign investors bought our securities at very low figures, and it may be they have concluded that this is the time to realize.

Whatever the reason, this gold is evidently wanted abroad. It may be that the owners who have had it here are afraid lest the banks would pay them in silver, and therefore they carry it to England. This view of the matter is taken by some of the Eastern journals. There is one thing sure, the scarcer gold gets in this country the more anxious will people be to get hold of gold mines and work them. California has the most extensive gold mining fields in the world, and there are plenty of claims that need capital for development, so the sooner investors come here and get hold of mines the better it will be for themselves and for our California miners.

The experiment of extracting or collecting the soda contained in the water of Owens Lake by pumping it into large vats excavated along the shore and allowing it to evaporate is said to have resulted satisfactorily. Mr. Yerrington is having more vats prepared, and operations will be conducted on an extensive scale next spring.

On the Mohave desert among the yuccas, grass is six inches high, a hitherto almost unprecedented occurrence.

U. S. of Colombia Mines.

In the PRESS of August 15, 1885, was an account of the mines in the U. S. of Colombia, which a correspondent in Honda, Estado Tolima, writes us is the first one he has seen in print concerning the country, which is without exaggeration. The mining outlook there is just now is very good in spite of the row which was kicked up by the radical party against the Government. Some of the gravel mines worked by English companies even made profits, although very little work could be done, (as the case was at Malpaso), as frequently the hands were pressed into the army. Some more gravel and silver mines have been

Endless Bed Double Surface.

The illustration on this page is that of an improvement in wood working machinery in the shape of an endless bed double surfacer. This is an improved design and has been adopted by the California Door Company and others in this State. It is designed for heavy, rapid and smooth work, being capable of double-surfacing 6000 feet of stock boards in ten hours. The bed is held upon four, large screws, thus having the firmness and durability of a solid bed machine.

The device for raising and lowering the bed, which is done by hand or power are placed on top; thus doing away with the inconvenience

Prehistoric Implements.

In prosecuting the work of gravel mining in this State several curious things have been found. The bones of mammoths and animals of past ages, tools and implements of nations which now have no place in the world, etc., have been found. At the last meeting of the California Academy of Sciences a stone cylindrical pestle was presented by Thos. N. Hosmer, of Bath, Placer Co. This cylindrical granite pestle is two and one-eighth inches in diameter and four and five-eighths inches long. It was found in one of Mr. Hosmer's claims in Volcano canyon. He was not actually present when it was found, but there is no doubt of its authenticity.

Volcano canyon has been worked and reworked for the last 30 or more years. The position where the pestle was found was in a deep place or gouge-hole, deeper than the surrounding bed-rock. The top earth and gravel had been long since worked off. This hole was filled with hard cement, gravel and boulders; the bed-rock had only

been reached in one place, as the gravel prospected poorly, and it was abandoned until they took hold of it this season and worked the hole out from end to end.

The pestle was found near the bed-rock imbedded in the hard cement gravel and the pick shows its mark. Although the implement is of granite, Mr. Hosmer says there is no granite in that section of country where it was found. Professor Davidson, who has given some attention to the finds of implements in this State, says if this stone really was used as a pestle, as appears likely, it is different from any of the many hundreds he has seen, in its purely cylindrical form, length and thickness.

CAMPBELL, Rigby and Dehere, of Smartsville, have been served with papers for an alleged contempt of the Superior Court of Yuba county for violating a debris injunction. The parties have been retaining all the debris by a system of dams and are trying to comply with the decision of the Supreme Court.

THE Virginia Chronicle says: It is rumored that a smelting furnace will be erected at Reno next spring to reduce the extensive deposits of carbonate ore in Washoe county and the refractory ores of the Comstock lode, providing Congress does not pass any law to further depreciate the value of silver.

THE "PHILADELPHIA" ENDLESS DOUBLE SURFACING MACHINE.

started up also of late, of which the most prominent are the Orita, Pompona, Maravilla, etc., and the silver mines of Calamonte, Rosio and La Maria, (new ones), make a very good showing. These mines are situated in the Department of Ambalema, State of Tolima. Our correspondent promises to give us a detailed account of this and other mines which will show that this section isn't very much out of the way to be known elsewhere. The great thing that is lacking in Colombia is capital, but that is the case everywhere. All the other old mines, of which there are many, are hard at work to make a good showing before the year is up.

CONGRESSMAN McKENNA will introduce a bill in the House at the first opportunity to encourage the manufacture of steel for modern army ordnance and other army purposes, and to provide heavy ordnance adapted to modern army warfare. The bill will provide for two plants for the manufacture of this ordnance, one on the Pacific coast and the other on the Atlantic.

It is rumored that the English syndicate that recently purchased the Blasdel group of mines, at Aurora, have paid up and deposited in the bank a cash capital of \$2,500,000.

THE Houserins mine, of Utah, has paid \$62,500 in dividends this year so far.

of getting down to the floor and reaching through running belts. They are near the scale and under full command of the operator. Quick and accurate changes of thickness can be adjusted without stopping the machine. The Goodell patent sectional pressure rolls and improved hinged, sectional pressure bars are used on this machine. These bars can be moving entirely clear of the knives while sharpening, and are as near the cutting edge as possible when the machine is in operation. These are practicable devices for feeding two or more unevenly sawed boards at the same time, and working all equally well.

The sectional rolls and pressure bars are the most important improvements in surfacing machines which have as yet been produced. The pressure bars for the lower cylinder are of special design, self-acting and adjustable. The under cylinder is of easy access for adjusting or sharpening the knives. The machine will surface up to 12 inches thick, and 20 or 30 inches wide, as may be ordered. The machine is called the "Philadelphia," and the sole agency for this coast is in the hands of the Berry & Place Machine Company (Parke & Lacy, proprietors), No. 12 California St., in this city.

THE Squaw Creek mines are "looking up," and many regard them as among the richest of Shasta county.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—*Eds.*

Montana Mines.

Meagher and Jefferson Counties.

[Written for PRESS by Our Traveling Correspondent, R. G. Huston.]

White Sulphur Springs, the present county seat of Meagher county, is situated 75 miles northeast from Helena and is near the head of Smith River valley. The hot sulphur springs from which the town derives its name are within the town limits and are considered among the best of this kind in the West. There is no doubt that they are very beneficial to parties suffering with rheumatism and many other diseases that flesh is heir to. The springs are reached by two lines of stages, one running direct from Helena via Canyon Ferry, White's Gulch, Fort Logan, and the other is by rail from Helena to Townsend and thence by stage up Deep Creek and across the valley to the springs. My trip was made by private conveyance to Canyon Ferry. From there I diverged from the direct road and visited the old placer mining camp of New York Gulch, taking in Oregon and Cave Gulches on the trip, but their greatness has virtually departed. Only a few men are now at work in these old diggings.

The present owners of the old Marshall ditch have been doing very well on Gurwell's Bar the past season and have a large quantity of the same class of ground ahead of them. Messrs. DeBoard and Black are at work in Clark's gulch, using water from the same ditch with satisfactory results. Following down Clark's gulch to junction we find Messrs. Woodward & Co., who are well satisfied with their past season's work in the foothills. They use the water from Oregon gulch, reserving it and running a pipe for three or four hours a day. Further down towards the ferry are Messrs. Vancamp and Boswell, who have been putting in a hydroelectric flume in Cooper gulch. They have not reached bedrock in the deep channel yet, but are sanguine that when they do once reach bedrock they will have as good a gold mine as they want.

Canyon Ferry, with its store and hotel, is run by an old timer, who seems to be the right man in the right place. Court Sheriff seems to know a man's wants and provide for them in good style.

The next camp we came to is Maggie gulch, the main creek of which has been a regular Waterloo to miners. Drain companies, one after another, have gone in there and spent time and money and have never yet discovered anything rich enough to pay to drift, but Marshall & Co. are having some good pay on the bars on the south side of the gulch, and have a large amount of ground patented. From all present appearances have a gold mine that will last an ordinary lifetime and then not be worked out.

At the mouth of Avalanches gulch is located J. V. Stafford's ranch, who has as fine a country home as you would find in older and more closely settled communities. Apples and plums, and Siberian crab, gooseberries, currants, strawberries, raspberries and blackberries are in abundance. There are about 300 acres under cultivation in wheat, oats, barley, etc., all of which yield abundantly with the aid of irrigation. He has also an unlimited range for stock in the mountains north of his ranch.

Passing on seven miles further we came to White's gulch, one of the old-time placer mines, the best of which has been worked out and the fortunate ones who amassed small fortunes have had ample time to spend them and to return to look for more; yet a dozen or two men still work around there and make an easy living.

Six miles further east we came to Old Confederate gulch, which at one time was the king of mountain placers. Mountain Bar is a place noted for the gigantic fortunes made in one season. Two parties who did not have credit for a sack of flour on Christmas drove out of the gulch during the next September with one ton of clear gold dust, and many others made handsome fortunes in the same place. At present there are only a few men there. There are two bedrock flumes. One is owned by Stafford, Buckingham and Nanno. The other is owned by Jas. King, and it is, without doubt, one of the best paying mining properties in the Territory to-day, as they are now at the end of Montana Bar, which was worked with short flumes. These tailings are a rich find for a flume company. There were some quartz discoveries a long time ago on some of the tributaries of Confederate, and a ten-stamp mill was erected on one of these properties some 16 years ago, but about the time the mill was finished there was a disagreement between the partners and the mill has never turned a wheel to this day. It stands a monument to some stubborn individual's "cussedness."

Meagher county, notwithstanding the decline of her placer mining interests, has experienced a continuous era of prosperity that is unparalleled in the western country. Two years ago her total assessed valuation did not reach \$600,000, and to-day it is \$6,000,000. This enormous increase is due to the immense stock interests. On the decline of Diamond City, the county seat was removed to White Sulphur

Springs, as it is more of a central point. The merchandise is confined to two houses, each of which carry mammoth stocks of everything that is needed in a well-regulated household, or that may be wanted by the festive cowboy, or the machinery and agricultural implements that are necessary to carry on a first-class farm. An old friend and patron of former Montana business days is the senior member of the firm of Spencer, Mayne & H. man, who are also lessees of the springs, hotel and baths, managed by Mr. Spencer, who is ably seconded by Mrs. S., under whose watchful care no patron will be neglected.

There is a move on foot to divide this county, and from the size and increase of wealth in the last ten years I think it is particularly desirable, as it will make a double number of offices to fill, and as that is a kind of a national poorhouse we have for men who are unable to cope with the world in other lines.

The town of White Sulphur Springs may yet be a very favorably located town in regard to mines. The Neihart mines are 40 miles north. The Yogo mines are about the same distance east, and there are some fine prospects in the Crazy mountains south of them, with the old placer mines of Thompson, Thomas and Benton gulches west. There is yet an opportunity for the county to develop. The smelter in Neihart was to start up last week and if that proves a success why the future is assured of that district.

Their heavy freight is all shipped into Livingston, 75 miles south. They have a railroad station 40 miles, but the road is so much better they ship entirely to Livingston. The *Husbandman*, whose interests are ably looked after by the Sutherland brothers, is a live country journal and they are pleasant affable gentlemen and deserving of the success that seems to be following their efforts. Townsend is a railroad town built up in the last three or four years and is favorably located for farmers of Missouri valley to get to for their general shipping point and also for their supplies. It has a number of fine large stores. The principal one is that of Messrs. Tierney & Co., who carry a large and varied stock of general merchandises. The old Indian creek ferry near this place is run by another old timer, J. L. Moore, who has laid aside the pick, shovel and pan, for the retired life of ferryman and stock dealer, and seems to be well satisfied with the change. Bedford is the next point of interest, being a railroad station located near the old Hogem placer diggings. They are still being worked some by two or three companies who are all doing well. Radersburgh, formerly the county seat of Jefferson county, and at one time the center of a fine shallow placer mining district, is now only a ghost of its former self, but they still live in hopes that their quartz interests will bring them out. One location, the Keating lead, has very rich and free milling ore at the surface and the owners made plenty of money out of it, but when they sunk down the vein ran into sulphurets so much that they could not save enough to make it profitable. But after lying idle for five or six years they are about to start up again and with the late appliances will be able to work it profitably. There are a number of other leads in this vicinity, but all have trouble in working on account of the large quantity of pyrites.

Indian Creek is eight miles north of Radersburgh and the old town of St. Louis has about disappeared. The gulch mining is about played out. The Little Giant quartz lead, located half mile above St. Louis, is still being worked with satisfactory results. It has been worked for about 16 years, and while it is not a fortune in a day it is regular pay. The rock runs from \$50 to \$75 per ton, the ledge varying in size from 4 to 10 inches. This lower tunnel is in some 1500 feet. They are now stopping from the upper tunnel, which is in some 900 feet. It is free milling gold, and the owners have a five-stamp mill over on Crow creek to which they transport their quartz and mill it. The owners are R. Roberts, J. Colhergh and Seiterly of Radersburgh.

Cost of Moving Railroad Trains.

EDITORS PRESS:—There is in the United States an association of scientists, artists and architects numbering among its members many names of the most eminent constructors and engineers in the world. These gentlemen call themselves the American Society of Civil Engineers. They meet periodically and listen to addresses delivered or read upon all matters pertaining to works of engineering. When they approve any paper which may be read before them they cause it to be printed for general circulation. No statement could emanate from or receive the endorsement of higher scientific authority than that of the American Society of Civil Engineers. On June 23, 1885, there was read before that society carefully prepared addresses upon canals and railroads, ship canals and ship railways, by E. Sweet and by E. L. Corthell, both members of that society, which have been published and since distributed and from which I take the liberty of making a few quotations for the information of the public through your valuable columns and in support of some of my previous statements.

I said that freight could be moved at a profit at half a cent per ton per mile; passengers at 2½ cents per 100 miles, or overland for \$1.00, and that the cost of moving trains in the United

States varied from 10 cents to 50 cents per mile run, according to condition of track, amount of grade, kind of fuel, number of cars in train, whether empty or full, rate of wages paid, and number of highly paid and unnecessary officials employed under the present competitive system. I think these quotations from the remarks of those gentlemen will go very far toward satisfying most minds that I speak within bounds when I say that the general average cost of moving trains one mile in the United States to-day is about 17½ cents, or less, per train per mile, everything included, and counting every locomotive moved as a train whether it pulls only a tender or 130 cars, and that the National Government could move all trains at very much less rates and make a profit where competing corporations would make a loss. That the United States Government could pay men much higher wages than any corporation and still move all passengers and freight for less than any corporation can ever be made to do.

The authorities referred to say, "In 1865 the cost per 100 miles run on the Pennsylvania railroad was \$16.48, and in 1881, \$6.02." "On the Pennsylvania R. R. main division and on the Philadelphia and Erie division the average cost (of moving freight) is about four mills (that is four-tenths of one cent) per ton per mile, including all expenses except interest on capital. This expense includes the transportation of local as well as through freights, handling at terminals and local stations, maintenance of permanent way, motive power and all the incidental and general expenses connected with the operation of the railroad." "On the same railroad, Susquehanna division, the actual cost of hauling (average of five consolidated locomotives on \$16,115 car miles) was 0.6 of a mill (that is six-tenths of a mill or six-hundredths of a cent) per ton per mile, including repairs to locomotives, fuel, stores and wages of train hands." "The average running time of railroads (trains) is at least 15 miles per hour."

"Ordinary sea-going steamers transport freight at a cost of about 0.5 (five-tenths) of a mill (or five-one hundredths of a cent) per ton per mile, expenses alone considered and not including interest, insurance, depreciation of steamer and profit, or three-tenths of a mill (or three-one hundredths of a cent) by the best examples of sea-going steamers." "The cost on a ship canal at two miles per hour (the economical speed) is against 12 miles per hour on the ocean, and with the same power required would increase the cost six times, or to three mills per ton per mile."

It may be stated broadly that railroad transportation in this country has been so far reduced in cost as to make it possible to haul freight at about four mills per ton per mile, including all expenses, even the terminal and other handlings of local and through freights; also, expenses and renewals, general expenses of management and the many other charges that go to make up the details of the cost of railroad transportation. The cost of handling freight is not perhaps appreciated by even railroad managers, for while immense and continual reductions are being made in the cost of hauling, but little advance has been made in reducing the cost at terminals and stations. It costs as much to handle a ton of goods at the New York terminal as it costs to haul it to Albany or Philadelphia. "Another important item in the cost of ordinary railway transportation is the labor." "An army of employees is required for all the various duties devolving upon railroads. Hundreds of returns and reports require a large clerical force." "The relations and connections with other roads in cars, goods, hack charges, etc., make a large amount of work necessary." "The assorting of goods for different destinations, the handling of cars on sidings and in terminal and division yards require not only a variety of labor but expensive power also." "The expenses of doing all this work is, however, so systematically performed and recorded on the best railroads that the cost of the various items is fully known." "The cost per mile on the best railroads is three mills per ton for through freight."

"All items for cost appear on page 81 Pennsylvania Railroad Report of 1885." "Deducting irrelevant items (such as handling and terminal expenses) we can properly reduce the cost 48 per cent, or to 1.56 mills, but a still further reduction is proper. Much larger loads are carried now—the ratio of paying to non-paying loads is greater." (There would be no non-paying loads on Government railways.)

"The above favorable conditions allow us to reduce the cost to one mill per ton per mile" (on ship railway). "The cost of towing sailing vessels * * * will be considerably more expensive than hauling them on the ship railway, and the cost of propelling a steamer by her own power will be, as has been previously shown, 3.0 mills per ton per mile, as against 0.5 mills per ton per mile by ship railway."

"The reasons for the reduced cost in railway transportation of late years are, improvements in the condition of railroads by better construction, better maintenance of track and in more economical administration; also, in the increase of the amount of freight hauled on one train, which is made possible by the increase in locomotive power and in the capacity of cars." "The trainload has increased about 75 per cent." "The capacity of cars has increased from 20,000 lbs. in 1855 to 1876 to 40,000 lbs. in 1882, and to 50,000 lbs. in 1885, and the master car builders have recently decided upon a standard car to carry 60,000 lbs." "The weight of cars on the Pennsylvania railroad in-

creased from 20,500 lbs. to 22,000 only from 1870 to 1881, but the load capacity increased from 20,000 lbs. to 40,000 lbs."

In making the foregoing quotations I have inserted some remarks of my own in parenthesis to make them more simple and easily understood for all, or more applicable to my subject. I will now repeat some of the more important items, and then begin my statements and arguments in another letter. From the foregoing we see that the freight-car of the past moved only ten tons, while that of the future now constructing will move 30 tons each. That on the best railways now in operation, everything included, the cost of through freight is three mills per ton per mile, and roads being continually improved and cost of hauling being annually reduced. A vast field for improvements of roads and reduction of costs will be opened up when the Government owns and operates the railways. We see that the cost of moving vessels through ship canals is three mills per ton per mile. Vessels moved on ship railway five-tenths of one mill per ton per mile. That in 1865 the cost of moving trains 100 miles was \$16.48. That in 1881 that cost had been reduced to \$6.02 "per train per 100 miles." That the actual cost of hauling freight on railways, without counting handling, has been six-tenths of a mill per ton per mile, and will be soon reduced by enlarging cars and using more powerful locomotives. That the average running time for freight trains in the United States is about fifteen miles per hour. That the cost of moving freight on the ocean in steamships is for ordinary ships five-tenths of a mill per ton per mile. First-class steamers, three-tenths of a mill per ton per mile. On ship canals, three mills per ton per mile. That on railways the average cost for moving all kinds of freight, local and through, has been about six-tenths of one mill per ton per mile, and including handling, terminal expenses and everything possible to think of, the cost has heretofore been only about four mills per ton per mile, and will hereafter be continually and steadily reduced.

These authorities prove that my statements are within bounds when I say the National Government can carry passengers at a profit from San Francisco to New York for 75 cents, or from Seattle, Washington Territory to Key West, Florida, or between the transcontinental stations most distant from one another within the United States "overland for \$1.00, and freight for one half a cent per ton per mile."

WILL D. SOUTHWORTH.

Mineral and Metalliferous Veins.

EDITORS PRESS:—I had just laid aside the excellent article on "Popular Fallacies Regarding Precious Metal Ore Deposits," contributed by Albert Williams, Jr., to the Fourth Annual Report of the U. S. Geological Survey (1882-83), this evening, when your edition of the PRESS for December 5th came to me, containing upon its second page an elaborate communication from Chas. F. Blackburn, who signs his address as Blackburn mining district, Idaho Territory, upon the subject which I have copied at the head of this letter to you: "Mineral and Metalliferous Veins." A portion of Mr. Williams' contribution which had made especial impression upon my mind was the following: "The work of the mining geologist in large part consists of demolition; in clearing away the rubbish of overthrown errors to obtain foundation room on which slowly to build a sound structure; in sifting and weighing a mass of speculations in the search for material. Some one puts forth a suggestion; it may be the sheerest piece of guesswork, but it finds its way into print, floats with the current literature of the subject, and by virtue of iteration becomes accepted as fact without perhaps ever having been seriously scrutinized." I was doubly impressed with the truth of the foregoing after I read Mr. Blackburn's effusion. The writer begins with the astonishing remark: "Most metals occur in veins associated with certain minerals." As I perused the article further, I was surprised to find a familiar paragraph. This puzzled me. I turned to my geological shelf in the library, took down several books, and in Le Conte's Elements of Geology, pp. 225 to 236, inclusive, edition of 1879, I found *verbatim et literatim* a large portion of what appears in Mr. Blackburn's dissertation. It is bad enough to have would-be mining experts forcing their own honest, although possibly unfortunate, convictions upon this people, to say nothing of that class of writers who are guilty of malpractice upon really good reading.

WALTER C. HADLEY.

Silver City, New Mexico, Dec. 10, 1885.

THE Newport Coal Mining Co. has made an assignment. The assets of the company are in the shape of the Oregon mine, which pays a monthly dividend of 50 cents per share, its surplus fund and the new steamer Arago. These are said to be worth a sum in excess of the liabilities.

THE heaviest dividend paying mine in the United States at present is the Calumet & Hecla, of Michigan, a copper mine. For the past ten months of this year it has paid \$1,200,000. The Ontario, a silver mine in Utah, comes second, with \$825,000 during the same period.

FOUR quartz mills are running now in Yuma.

MECHANICAL PROGRESS.

Working Iron and Steel.

Jersmiah Heed, in a recent number of *Iron and Steel*, says: When a certain range of temperature, steel can be more successfully worked than iron; but that range is narrower. Thus, at the temperatures familiarly known as cherry red, a good steel plate can be bent double and then redoubled crosswise. An iron boiler plate is considered good if it bends double with the fiber and at a right angle across, at a full red heat. Steel plates are best worked at a low heat, iron ones at a somewhat higher heat. At a welding heat, steel plates require the utmost care to avoid burning or fusing, after which they become quite brittle. A number of steel plates which I saw lately being dished out to a very awkward form between two dies under a steam hammer were mostly failing. The men were advised to lower the temperature to cherry red, and the remaining plates all stood the test.

Steel is less easily welded than iron. Thus, the blow holes, or piping, which occasionally occur in ingots are never welded up in subsequent rolling. They become enlarged, and are the cause of the lamination which is not unfrequently found in steel plates.

Mr. Adamson, in the course of his paper read at Paris, in 1878, gave it as his experience that some steel could be welded, but not all. He believed that for this purpose the carbon contained should not exceed 0.125 per cent. It is still true that all steel will not weld with ease and certainty; and it is not yet quite clear wherein the difference lies. It must not be forgotten that there are welds and welds. A good weld is one where the welded pieces will afterwards bear the same cold bending through the weld as through the neighboring solid part. Probably there are very few welds, though to all appearances perfect, which would stand this test.

As an instance of good practice in welding steel, I may mention that at Messrs. R. & W. Hawthorn's works at St. Peter's, Newcastle, marine boiler flues, seven feet long, are soundly welded at one heat. A V-groove joint, carefully planed out, is adopted; and certain fluxes are used to fuse the scale, which would otherwise prevent adhesion of the surfaces. Flue rings, conical tubes, and other details of boiler work, involving welding and subsequent flanging, can now be made of suitable steel almost as easily as of iron; and when made they are incomparably better. For to make a welded and flanged tube of iron not more than 5-16 inch thick, a very high quality of iron must be used; and even then the tube will be unable to stand subsequent rough usage, such as setting cold to snit deviations in the dimensions of the flues. The repeated heatings undergone during welding and flanging have indeed taken the "nature" out of the iron, and left it brittle. But steel tubes, when finished and annealed will stand battering about cold, without any fear of damage whatever.

The Tempering of Metals by Cold Flow.

The tempering of metals during the operations of drawing and spinning are well known to all conversant with the details of such work. Cartridge tubes must be annealed between the several operations. Ward's process of making bolts by the cold flow of iron also requires that such bolts be annealed before the threads are cut; even in flat plates it is known that the roll temper of thin flat plates of brass or steel is very uniform. It is stated that when Mr. A. H. Emery, of New York, was engaged in making his testing machine for the United States Government, the result of exhaustive experiments upon this subject showed that the temper of steel plates as they are rolled is more uniform than is possible by any later tempering. According to *Van Nostrand's Magazine*, some recent experiments on the substitution of low steel for copper and brass in the manufacture of cold-drawn tubing have shown that, in the process of drawing, the steel becomes very hard and of increased tensile strength. This new feature is extending the uses to which low steel can be applied. A cannon has been made from such metal by drawing a six-inch tube with walls one-half inch thick; a seven-inch tube was drawn cold, and, when warmed, was forced over the first tube; a third tube was fashioned in like manner eight inches in diameter, and, when forced over the other two, completed a six-inch gun, with walls one and a half inch thick, and cylindrical in outline. It is claimed that a gun of this dimension, which has been submitted to the United States Ordnance Board for examination, has sustained a water pressure of 75,000 pounds per square inch. This corresponds to a tensile stress of 100,000 pounds per square inch of metal. Admitting, however, that the gun did withstand such a pressure once, it is no measure of the resistance which can be relied on as a safe working pressure of the impact of explosion of powder.

TEMPERING SPRINGS.—A good way to temper small coiled wire springs, as practised in factories where many have to be done, is to heat an iron pot filled with lead so that the lead is a full red, or sufficiently hot to heat an immersed spring to the requisite temperature for harden-

ing, which can be done by quickly immersing the hot spring in water or lard oil. Then, for drawing to a spring temper, heat a small vessel of linseed oil to its boiling point. Dip the springs in the boiling oil for a few seconds—time according to thickness—and then into cold oil.

Sharpening Miners' Drills.

A correspondent to the *American Machinist*, replying to an inquirer through the columns of that journal, relative to tempering miners' rock drills, writes as follows:

He will find his drills to stand all right if he uses good steel and cuts off from one-half of an inch to one inch each time the drill is repaired.

I have personally sharpened drills for a steam drilling machine, and noticed that a new drill made from a fresh bar of steel would stand admirably, but when I renewed it by hammering the edges sharp, it did not stand quite as well. The next time it was renewed by hammering it was still poorer, until finally, when thus renewed four or five times, it did not stand at all. Sharpening by filing did about the same.

I had noticed that at the Hoosac Tunnel, about an inch was cut off from the cutting end each time a drill was sharpened; and the whole work of forming the drill bit gone through with. I regarded this as extremely foolish at the time I observed it. A year later, when I came to repair rock drills, I said I would have no such fooling and wasting of steel and labor, and so did not cut off any at first. But I soon found that the Hoosac Tunnel practice was correct, for when my drills began to fail to do good service after being renewed several times, I studied the matter some, and thought I would try cutting off. As soon as I commenced this, my drills were all as good as if first formed on a fresh bar.

I then studied this matter more and soon came to the following conclusions:

1st. Each time a piece of tool steel is hardened it loses about one tenth of its life and goodness.

2d. That the strength of the steel, as well as the wearing quality, are both injured about in the same proportion by repeated hardening.

3d. That a tool requiring repeated dressing and hardening, such as rock drills, cold chisels, lathe tools, etc., should be each time hardened for as short a portion of the length as possible, so that at any given time the steel at the point of such tool should have been hardened as few times as possible, and that in many cases it is advisable to cut away a portion of steel to bring the cutting edge down to the first hardening.

These facts should be kept in view by all tool-makers. A tap, for instance, which has been hardened and drawn a little too low, is about the same as ruined, because to try again by re-hardening, etc., takes another tenth of the goodness of the steel away, and this cannot be spared from a tap, because at the best the tap is none too strong.

If the old Hoosac Tunnel drill department could be brought in to testify, it probably could give us a great deal of valuable information on how steel is affected by repeated hardening.

Molecular Change in Iron.

The *Locomotive*, which chronicles the experience of the Hartford Boiler Inspection and Insurance Company, in a late issue, under the heading of "Crystallization of Iron," points out that if a boiler be well made, of good material and properly cared for, there need be no fear of its becoming unsafe through molecular change in the plates during the ordinary lifetimes of the boiler. Any such change it attributes to over heating of originally bad material, or of good material when the scale or sediment deposited by the feed water is not properly cleaned out.

In the same issue that journal illustrates a properly designed arrangement of steam connections for a battery of boilers, so that the effects of expansion, and any settling of the boilers after they have run a short time, will not cause rupture. It advocates the use of wrought-iron pipes, as in every way better than cast-iron. The plan illustrated shows vertical risers, not less than three feet high, attached to the nozzles by means of flanges, and from the upper ends of these risers, pipes are led horizontally backwards into the main steam pipe, which runs parallel to the plane of the risers. In the horizontal pipes connecting the risers and main steam pipe, the stop-valves, one to each boiler, are placed, and these have flanged ends, so that they may, when necessary, be easily removed, without disturbing any other portion of the piping. By this arrangement the spring of the pipes will compensate for any movement of the boilers. We have in our own experience seen not a few batteries of boilers connected directly to the main steam pipe by vertical pipes, and there was constant trouble, until a change was made in accordance with plans resembling closely those described above.

FORGING BRASS.—A correspondent of the *Scientific American* asks: "Can brass be worked in a drop at all? That is, can it be drop-forged the same as iron can?" The journal mentioned replies that soft brass can be worked very well in a deep press, but not to the same extent as hot iron or steel.

SCIENTIFIC PROGRESS.

How Some Soils are Formed.

Mr. Ernest Ingersoll in *Science*, of November 27th, describes the plains of British America as follows: Striking contrasts present themselves to the experienced eye between the plains of British America, through which the lately finished Canadian Pacific railroad runs, and those crossed by the transcontinental lines in the United States. In the first place, they are larger. It is more than 1000 miles from where the forested granites of Keweenaw dip under the silurian prairie-floor in the Red River valley to the first escarpment of the Rocky mountains. In Kansas it is hardly half as far between the wooded regions and the foothills of Pike's Peak.

Another feature is the prim-like look of it all, save certain far-western tracts. The grass is dense and long. Flowering herbage is profuse. West and south of the South Saskatchewan this gives place to a greater, more "plains"-like scantiness of vegetation, to be sure, but nowhere is the barrenness and aridity of the southern plains equaled.

This is due to the greater moisture in earth and air, and to the extraordinary fertility of the soil. Manitoba produces an average of 22 bushels of wheat to the acre—four to five bushels in excess of the average of any other similar space on the continent. The soil is coal-black and declares its richness at first sight. Dr. Robert Bell, of the Canadian Geological Survey, discussed the causes of this fertility before the Canadian Royal Society, May 23, 1883. He pointed out that the materials were the best possible, having been derived from the glacial drift of the North, mingling sand and gravel with the cretaceous marls spread over all British America. Having this favorable constitution, Dr. Bell assigns to the moraine this chief agency in the formation of the thick top-layer of vegetable mould which is now the joy of the farmer.

In the Assiniboine valley the moles have thrown up almost every foot of the soil into little hillocks, each containing a large shovelful of earth, and burying completely the grass and vegetation over a space a foot or more square. The vegetable matter thus buried decays, and becomes incorporated with the soil, so that this process is analogous to plowing under the soil. In making their burrows they select the finer material and cast it up to the surface, leaving behind the coarser. The effect of this is similar to that alluded to by Darwin of the earthworms (which do not exist in the northwest territories), since, in the course of time, all the stones are buried. Their labor is supplemented by the gophers, spermophiles and badgers, the last named digging deeply and heaving up large quantities of gravelly subsoil, which the moles work into and improve, while all bury much vegetable rubbish, as nests and food. This beneficent animal agency nearly ceases when the elevated "third steppe," called the Grand Coteau du Missouri, is reached, and when the mountains are approached the soil is clayey.

FALSIFYING HISTORY.—Volume 19, page 326, of the new edition of the "Encyclopedia Britannica" contains an article entitled "Polar Regions," by Clements R. Markham, in which reference is made to the geographical work of the Greely Arctic expedition, as follows: "Lieut. Lockwood made a journey along the north coast of Greenland, and reached a small island in 83° 24' [N. Lat.] and 40° 05' [W. Gr.]. Dr. Pavy and another went a short distance beyond the winter quarters of the Alert, and a trip was made into the interior of Grinnell Land. But all this region had been explored and exhaustively examined by the English expedition in 1875-76." The italics are our own. Attention has recently been called to this statement by the author, Charles Lanman, of a little memorial volume on his life and arctic work of Lieut. James E. Lockwood. It is a matter of no little astonishment that any writer or publisher of a standard work like the one referred to, should allow haste or international feeling, or any other impulse to lead to such a palpable falsification of history or do such gross injustices to a scientific explorer who lost his life from privation in the field of his labor. No act connected with polar exploration is better substantiated than the fact that Lockwood not only reached the highest latitude ever attained by any explorer, but went fully 100 geographical miles further north than any other explorer of any nation ever reached. It is furthermore well known that no "English expedition" ever "mapped, explored and exhaustively examined" the region alluded to.

THE CHANGE OF FOLIAGE.—The immediate cause of the change in the foliage during the fall lies in the lessened action of the breathing organs or pores of the leaves, resulting from a loss of warmth and light due to the shorter days. The natural stimulants to vegetation are withdrawn. Shortly before the fall of the leaf, a very delicate layer of cellulose starts from the side of the stem and grows downward, completely separating the leaf from any participation in the life circulation of the plant. This explains the smooth surface exposed on separating a mature leaf from its branch. With the cessation of the circulation of the sap, the leaves no longer absorb carbonic acid gas and give off oxygen. The great natural process of deoxidation is arrested, and finally reversed—oxygen

is absorbed. The chlorophyll, or leaf green, which gave color to the leaves during the earlier part of the season, is now oxidized and changed to xanthophyll, or leaf yellow, and erythrophyll, or leaf red.

These new salts contribute nothing to the nourishment of the leaf. No carbonic acid is absorbed from the atmosphere, and the leaf soon dies and falls to the ground. This difference in the coloring of the leaves depends upon the local conditions, which hasten, modify, or retard this chemical reaction. In the so-called evergreens, no transverse cell formation takes place, and the leaf is never separated from the circulation of the main tree. They also evaporate less in proportion to their leaf surface than ordinary trees. Their more sluggish circulation is less dependent upon climatic influences.

A THINKING MACHINE.—ALMOST.—A cultivated gentleman of French descent residing at Gallipolis, O., who has been an invalid for several years, has just received a patent for an invention of more than ordinary merit and of peculiar character. It excites the wonder and admiration of all who behold it. Many declare it the equal in general utility of the sewing machine or telephone. It is perfectly wonderful in its operation, and yet so simple in its action that a child can learn to use it in a few minutes. It consists of a pair of scales which announce with unerring accuracy the value of any number of tons, pounds or ounces at any price. For instance, a ham is placed on the scales. It weighs 12½ pounds and the price is 12½ cents per pound. A sliding weight is moved along the scale beam until the ham is balanced. In this notch where this weight stops will be found the worth of the meat in dollars and cents to a fraction. Again, suppose a grocer is asked for 50 pounds of tea. This price is 78 cents. One indicator is set at 50, the amount wanted, the other at 78, the price of the tea. Tea is poured into the scoop until this scale is balanced, when the quantity of tea is found to be correct as if several minutes time had been consumed in making this calculation.

A PERFECTED SEWAGE SYSTEM.—Shewsbury, England, has solved the sewage problem to perfection. As the sewage enters the works, clay, charcoal and blood are added as decolorizers, and after thorough mixing a solution of sulphate of alumina is added, by which the dissolved and suspended impurities are quickly precipitated in one or the other of the settling tanks, from the fourth of which the water runs without further treatment into the river. The sewage as it enters the works contains about 37 per cent of suspended organic and inorganic matter, but in the effluent water there are found only the merest traces of either. By experiment it has been found that in this water fish will live for months. This deposit is then removed from the tank, and by means of pressure and artificial heat is deprived of its moisture till it attains this consistency and appearance of dry earth, in which condition it meets a ready sale as "guano."—*Manufacturers' Gazette*.

ICE FROM THE SOIL.—Many of our readers have no doubt seen and admired that beautiful appearance which is often presented in the early morning after a cold and freezing night, when the ground is seen covered with little filaments of ice from a half an inch to two inches in length. This phenomenon most frequently occurs after the first frost succeeding a heavy rain, when the ground is thoroughly saturated with water. In viewing it many have no doubt wondered how they were formed, without being able to solve the problem. It is explained as follows: The little filaments are pressed out from the soil through small openings by the expansion of water in the ground as freezing proceeds. The size of the filaments depends upon the size of the openings through which they have been forced by expansion from behind, and the flutings with which they are covered correspond with irregularities in the walls of the openings through which they are forced.

HOW TREES EFFECT THE RAINFALL.—In the official report of the geological survey of Wisconsin, is an account of the determinations made by Dr. J. M. Anders, of the amount of water pumped from the earth by trees. He finds that the average exhalation from soft, thin-leaved plants in clear weather amounts to about one and a quarter ounces troy per day of 12 hours for every square foot of surface. Hence, a moderate sized elm raises and throws off seven and three-quarters tons of water per day. In the report the facts are applied to what is going on in America, where certain inland fertile districts are becoming converted into deserts by wholesale clearings, and in other places, such as the plains of Colorado, where five or six years of irrigation and planting have already produced a measurable increase of rainfall. It is maintained that the deserts of Syria and Africa are the results of cutting down trees, and that original luxuriance may be restored by skillful replanting.

NATURE EVER THOUGHTFUL.—The utility of tears to animals in general, and particularly to those which are exposed much to the dust, such as birds which live amid the wind, is easy to understand. The eye would soon be dirtied and blocked up had not nature provided this friendly everflowing stream to wash and refresh it. A very little fluid is necessary to keep the eye always clear and clean.

Passing Events.

With this number of the PRESS the volume is concluded, and we are ready to start in again on a new one with the expectation of constantly improving the paper.

During the past week very heavy rains have fallen over a large area in this State, in some places causing serious damage. In this city, on Monday morning, between two and three inches of water fell within a few hours, hursting the sewers, flooding cellars, and causing considerable inconvenience and loss. It was the heaviest rainfall ever experienced in this city while it lasted.

The transfer of the control of the South Pacific Coast Railroad to Jamee G. Fair, which occurred this week, will probably cause the building of two or more extensive cable railroads in Oakland.

The silver question is being vigorously agitated just now, and Congress will soon deal with the subject. Wm. M. Evarts has taken the side of the advocates of silver, and will take issue with the views of the administration on the subject.

Large shipments of gold are being made out of this country to Europe just now.

These are holiday times, and the storekeepers are reaping their harvest, but general business and labor interests continue depressed.

Close of the Volume.

This number is the final one of Volume LI of the MINING AND SCIENTIFIC PRESS. The paper is the oldest one devoted to the interests of mining in the United States. It has, since its establishment over a quarter of a century ago, constantly devoted its columns to the advancement of the legitimate mining industry and kindred interests, and to popular science, mechanics and inventions.

The very full and carefully prepared index which occupies the last page of this number is an indication of the scope and variety of the contents of the volume and shows the trouble we have taken to collate technical and general information of all kinds likely to be of value to our special class of readers.

Most of the inventions of note, originating on this coast, we have described accurately, making a specialty of this as we always have done. The index gives a complete list of all Pacific Coast inventors and patents for the six month's time covered by the volume.

With regard to mining matters we have, each week, given a condensed summary of current news of mine, mill and smelter. The news we have gathered from all Pacific Coast States and Territories, and given it in such a form that the reader could tell at a glance the state of affairs in the various camps and mining centers, and watch the progress of development in any particular mine. We have also kept close watch on all improvements in the mechanical appliances of mining, describing and illustrating in detail those that we thought had merit. In metallurgical matters we have been specially anxious to describe all that was new. New processes, methods and plans, and new metallurgical appliances, etc., have been described for the benefit of those of our readers interested in those subjects. These features alone make the PRESS worth more than its subscription price to its mining readers. Unless a man takes a paper of this character he will find that many improvements are constantly being made in his line of business about which he is ignorant. We obtain information of this kind from home and foreign sources as well, and in this way get the experience of others to benefit our own people.

The PRESS is certainly worthy the support and encouragement of the industrial progressive classes of this coast. Our endeavors should be seconded with subscriptions and correspondence. The long experience in this class of journalism of the proprietors and editors is a guarantee that the interests of those we serve will be conscientiously and intelligently guarded. Our advertisers now comprise the best firms in special lines, and many of them have been in our columns for many successive years; a proof that their enterprise has brought its due reward.

We have several traveling correspondents who are constantly gathering material of interest to our readers from the various camps, and our other correspondents are many and increasing. The PRESS may be considered a necessity to persons engaged in mining on this coast.

In the coming year we hope to make the PRESS even more interesting and valuable than ever, and it behooves those who are not already on our lists to add their names at the commencement of the volume.

The Amoor Gold Fields.

Not long since we gave an account of the discovery of somewhat extensive gold fields on the Chinese side of the Amoor river. Naturally the Russians who had been working the gold claims on their own side of the river crossed over into Chinese territory and started to prospect there. At first there was no objection made by the Chinese, but numbers of foreigners, attracted by the reports of the gold finds, began to move into the region, until the Governor of the Amoor provinces began to consider their presence a source of danger. Now the foreign colony has been broken up, and the Russians and others have been driven across the river again by the Chinese. Several thousand miners were expelled.

The wealth of the region in question is not doubted. The gold fields of the Amoor on the Russian side have yielded largely, and the new ones on the Chinese side are reputed equally as good and more extensive. There are coal veins in the mountains thereabouts also, but restrictions have been placed upon them as

well, and foreigners are forbidden to work them without official permission, which means the payment of money.

Manganese.

Manganese is found in heavy deposits in California and Nevada, and occurs in greater or less quantity in the Rocky Mountain region. The only deposit that has been worked to any extent is that on Red Rock, in the bay of San Francisco, but that has not been worked since 1866, as the ore cost more than it came to. The following comprise the other localities in this State where the mineral has been observed: Near Angel's Camp and at Redroad Flat, Calaveras county; abundantly at Corral Hollow, Contra Costa county; near Saucileto and Tomales, Marin county; Sweetland, Nevada county; Mt. St. Helena, Napa Co.; Argentine and Mariposa Hill, Plumas county; near Colton, San Bernardino county; Bernal Heights, near this city; at several places in Santa Clara and Sonoma counties, and near Columbia, Tuolumne county, where pieces of ore weighing over 100 pounds have been picked up on the surface of the ground.

The chief use of manganese ores is as a ready and easily available source of oxygen. For this reason the dioxide is the only valuable constituent, because it can be made to give up its oxygen by several means. Advantage is taken of this oxidizing power of the dioxide in the preparation of chlorine and bromine. It is extremely difficult to separate these elements from other elements with which they are ordinarily in combination. It is a simple matter, however, to obtain hydrochloric acid, and when manganese dioxide is added to this, its oxygen unites with the hydrogen, forming water, and leaves part of the chlorine free. As it is very difficult to transport chlorine in its ordinary gaseous state, it is passed over slaked lime, and thus made into "bleaching powder," which is a mixture of chloride and hypochlorite of calcium. Bromine is made by a similar process, but as it is a liquid it is not necessary to convert it into a substance analogous to bleaching powder. These processes, which consume probably three-quarters of the manganese mined in this country, are carried on at several places near Pomroy, on the Ohio river, and at a few other points in the United States. When manganese ore richer than 70 per cent is obtained, it is usually found profitable to send it to England for the manufacture of bleaching powder, and a small proportion of the yearly supply is thus annually exported. This is the only case of the exportation of manganese. Manganese ore is also used as an oxidizing agent in boiling linseed oil and varnish. When linseed oil is boiled with powdered manganese dioxide, the oil takes up a certain amount of oxygen and becomes thick, drying rapidly. Manganese dioxide is also used in the preparation of oxygen, but only when mixed with chlorate of potassium; because manganese dioxide requires a very high temperature when heated alone before it will give up its oxygen. When heated with potassium chlorate the latter yields its oxygen at a comparatively low temperature, the dioxide serving only to distribute the heat through the mass.

So far as can be ascertained, these are the only uses for which the native ores of the United States are at present available. There are two or three uses into which the manganese itself enters, but for these foreign ores are used altogether. Considerable quantities of manganese iron ore are imported, principally from Carthagena, Spain. The ore is brought as ballast in sailing vessels and steamers coming to American ports in search of cargoes. Probably the largest amount comes to Baltimore, but some is also received in Philadelphia and New York.

THE Mechanics' Institute Trustees have decided to have the rooms on the upper floor of the building on Post street, now occupied by private parties, vacated, and appropriate them to the drawing and mechanical classes.

THE output of Leadville is expected to reach \$12,000,000 for 1885. The place has about 100 producing mines, producing about 1000 tons per day of the value of \$40,000.

GRANITE CREEK, British Columbia, where there is now a gold excitement, we learn is in the Similakeen region, one of the eastern districts in the interior.

Lead Smelting—No. 3.

Ores.

The ores of Leadville are remarkably pure argentiferous lead ores. They are locally divided into two general classes: the "sand carbonates", which are loose, sandy masses of carbonate of lead with chloride of silver, and "hard carbonate", which are masses of porous siliceous material with a varying proportion of hydrated oxides of iron and manganese, carrying carbonate of lead and chloride of silver, and sometimes containing a considerable proportion of unaltered argentiferous galena. As a rule, with the exception of mechanical mixtures of clay and varying proportions of iron and silica; they contain but few foreign ingredients. Intimately associated with the carbonates is generally a little pyromorphite or chlorophosphate of lead, amounting in one exceptional case to 10 and in another to 30 per cent of the whole. Sulphate of lead also occurs in small quantity, with small and variable amounts of oxidized compounds of copper, arsenic, antimony, and manganese. The latter is often abundant, and is associated with or replaces iron oxide. Ores which are rich in manganese are generally poor in silver. The galena is frequently covered by a coating of carbonate showing clearly the alteration of the sulphide, first to sulphate, and then to carbonate. In some few mines bismuth and vanadium ores have been found. But a small proportion of the ores melted is furnished by districts outside of Leadville. Of this the greater part comes from Ten-Mile district, in Summit county, and especially from the Robinson mine, whose deposits carry much pyrite and zincblende. The silver in the oxidized ores is present in combination with chlorine, bromine, and iodide, either as chloride, chloro-bromide, or chloro-hydro-iodide, as the analyses of specimens from several mines made in the laboratory of the United States geological survey at Denver show.

	R. E. Lee Mine.	Amie Mine.	Big Pittsburg Mine
Chloride of silver.	21,589	15,755	99,985
Bromide of silver.	77,986	84,091	None.
Iodide of silver.	0.425	0.154	0.035

Large masses of chloride of silver, or horn-silver, have been found, and on several occasions tons of ore have been taken from the R. E. Lee mine assaying from 6,000 to 15,000 ounces of silver to the ton and almost entirely free from lead. According to Mr. Guyard, sulphide of silver is sometimes present in small quantity.

The Leadville ores in general contain little or no gold, its presence not being easily detected in the ore itself, but only being shown in the final product. The average daily output of the mines in 1880 is placed by Mr. Guyard at from 700 to 800 tons, and the total smelting capacity of the furnaces 700 tons per diem.

A Science Fund.

A fund has been established by Mrs. Elizabeth Thompson, of Stamford, Conn., "for the advancement and prosecution of scientific research in its broadest sense." The fund now amounts to \$25,000. As the income is now available the Trustees are desirous of receiving applications in aid of scientific work. This endowment is not for the benefit of any one department of science, but it is the intention of the Trustees to give the preference to those investigations not already otherwise provided for, which have for their object the advancement of human knowledge, or the benefit of mankind, in general, rather than to researches directed to the solution of questions of merely local importance. The Trustees are H. P. Bowditch, Wm. Minot, Jr., Francis A. Walker, Edward C. Pickering and Chas. Sedgwick Minot, the last named being Secretary, with address at 25 Mt. Vernon St., Boston, Mass. Applications for assistance from this fund should be accompanied by a full statement of the nature of the investigation, of the conditions under which it is to be prosecuted, and of the manner in which the appropriation asked for is to be expended. The first grant will probably be made early in January, 1886. Here is an opportunity for those engaged in scientific research to receive pecuniary assistance in their labors, provided the object meets the approval of the Trustees of the fund.

THE State Line mill at Gold Mountain is running twenty stamps steadily, and the enterprise is said to be prospering every way.

Intermittent Furnaces.

The accompanying engravings show the last survival of the old intermittent quicksilver furnace in its most perfect form, as in use at the New Almaden quicksilver mines, Santa Clara county, in this State. The horizontal and vertical longitudinal sections show the furnace proper. In the left end of these figures (in the former), A to B is also shown the first condenser, and combined ore-drier.

The ore-chamber which forms the main body of the furnace is also shown in cross-section C D. It is separated from the fire-place on the right and the vapor-chamber on the left by pigeon-hole walls. These walls have in plan the form of an arch with the convexity towards the ore-chamber, as they serve to keep the ore from the vapor and fire-chambers.

Mr. S. B. Christy, in a paper read before the American Institute of Mining Engineers, described the details of this furnace. The ore is charged into the ore-chamber through the top of the furnace, being lowered in a Mexican ore-basket by hand. A series of "channels" or flues is built along the bottom across the ore-chamber, in continuation of the apertures in the pigeon-hole wall, with lumps of coarse ore. In former times adobes were used for this purpose. When the first series of channels has been built, a layer of coarse ore two or three feet thick, according to the size of the fragments, is charged into the furnace; then another series of channels is built, and so on to the top of the furnace. To counteract the natural tendency of hot air to roast the upper rather than the lower layers of ore, the channels are made smaller and farther apart in the upper layers of ore, and a certain amount of tierras and soot from the condensers is added to the coarse ore for the same reason. The ore-chamber is 12 feet long by 9 feet wide, and 17 feet six inches high, inside measures; and the charge of ore is 80 to 100 tons. The discharge-ports or draw-holes are four in number, two on each side of the furnace. They are bricked up during the roasting of a charge, except a peep-hole, kept tight by a luted brick. It will be noticed that the final discharge-opening for the fumes has its bottom on a level with that of the ore-chamber, and its top at a height of six feet nine inches above the floor. This is to counteract the upward tendency of the gases already mentioned.

The operation of these furnaces as now managed (without adobes) is as follows:

1. Charging.—This takes the labor of 8 men for one day. As already described, the coarse ores (*granza* and *terrero*) are used to build channels, the coarse ores are next piled in indiscriminately, then another series of channels, and so on, till a layer of soot and *tierras* fills the furnace to the top. The draw-ports are then bricked up; on top of the charge, pieces of old sheet-iron are laid; on these is placed a two or three-inch layer of straw manure, and on the latter, a layer of moist clay of about the same thickness. The furnace is then ready for the second period.

2. Roasting.—This requires, in most cases, the labor of one man per shift of 12 hours for five days and four nights. Besides attending to the firing, the man in charge of the furnace lutes any cracks that may appear in the peep-hole doors, and from time to time sifts ashes

over any cracks that may form in the clay luting that covers the top of the furnace.

3. Cooling.—This, of course, requires no labor. When the firing is stopped, the furnace

INTERMITTENT QUICKSILVER FURNACE.

is allowed to cool for three days and three nights, the air passing through it into the condensers all the time, removing any quicksilver that may be still retained in it, and cooling the ore so that it may be handled by the men.

4. Discharging.—For this the labor of four men for one day is necessary. The top is removed to create an upward draft through the furnace; the discharge-ports are broken open; and the men draw the spent ore through the ports into the slag-cars.

In this manner a charge of ore is finished in just ten days; so that three such charges may

be put through in one month. Formerly, when the intermittent furnaces only were used, less time was given to the roasting and cooling periods in order to increase the production. As a consequence, the ore was not always thoroughly roasted; and the men who charged and discharged these furnaces suffered considerably from the heat and the fumes of the mercury. The time of roasting and cooling such a furnace should, of course, be greater with rich than poor ores; and the fact brought out by the present management that sufficient time was not allowed to roast rich ores in these furnaces explains in large part the losses and evils formerly connected with their use. Thanks to the Huttner and Scott furnace, it is no longer necessary to treat tierras in the intermittent furnace. If it were necessary to treat a full charge of adobes, this would, according to the results for 1875, add 95 cents per ton to the present cost of \$1.37, or nearly 70 per cent to the present cost of roasting in the intermittent furnace.

PATTERSON MINING DISTRICT.—A correspondent writes us that in this Mono county camp little work has been done in prospecting, on account of the late severe storm which occurred on November 21st, the snow rendering it impossible to ship ore to the mill. The only work of any note done in the camp was that by the Patterson Con. Co., their work being confined to two of their claims, the "P. & C." and Monte Christo. On the above mentioned mines a joint tunnel has been run, crosscutting the ledge from the surface at a depth of 75 feet.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 262 Market St., S. F.

FOR WEEK ENDING DECEMBER 8, 1885.

- 331,759.—TIME DETECTOR—E. Bernaa, Los Angeles, Cal.
 331,861.—ROTARY CUTTER FOR DREDGERS—J. H. Bolles, S. F.
 331,865.—LOST MOTION DEVICE—W. J. Butler, Salinas, Cal.
 331,871.—HORSE COLLAR—S. B. Davis, Eureka, Cal.
 331,775.—FOOD COMPOUND—A. A. De Puy, S. F.
 331,873.—BALING PRESS—M. W. Dursi, Wheatland, Cal.
 331,967.—TWO WHEELED VEHICLE—J. A. Gallagher, Stockton, Cal.
 331,877.—SAW SET—R. F. Gibbs, S. F.
 331,891.—CARTRIDGE PACK—J. C. Kelton, S. F.
 331,892.—CHECK REIN ATTACHMENT—J. C. Kelton, S. F.
 332,157.—JOURNAL BOX—Geo. H. Kinzer, Grants Pass, Or.
 331,902.—CABLE GRIP—W. H. Milliken, S. F.
 332,167.—MAP OR CHART ATTACHMENT—Geo. F. Schild, Vallejo, Cal.
 331,917.—FEED WATER PURIFIER—A. J. Stevens, Sacramento, Cal.
 331,929.—DREDGER—J. N. S. Williams, S. F.

FOR WEEK ENDING DECEMBER 15, 1885.

- 332,473.—AMALGAMATOR—M. J. Amick, Portland, Oregon.
 332,479.—SUSPENDERS—Geo. H. Boyd, Marysville, Cal.
 332,373.—CAR TRUCK—W. T. Browne, Stockton, Cal.
 332,327.—BOOKMARK—W. F. Clark, S. F.
 332,590.—EXTENSION TABLE—S. E. Claussen, Portland, Or.
 332,640.—BOTTLE COVER MACHINE—E. K. Cooley, S. F.
 332,648.—SAFETY KEY FOR GAS BURNERS—J. & J. H. Dutton, S. F.
 332,333.—DEVICE FOR FLUSHING SEWERS—A. T. Eilford, S. F.
 332,507.—LADY'S COLLAR—Estelle Fiske, S. F.
 332,508.—BEER DRAWING APPARATUS—P. F. Gardner, Hill's Ferry, Cal.
 332,397.—CUT-OFF VALVE GEAR—J. J. Holland, S. F.
 332,261.—WINDMILL—A. W. Lane, Janesville, Cal.
 332,403.—OYSTER OPENING MACHINE—Constant Leduc, Denver, Col.
 332,418.—HYDRAULIC ELEVATOR—P. F. Morey, Portland, Or.
 332,554.—FIRE ESCAPE—I. D. Pasco, Belmont, Nev.
 332,434.—BRAKE LEVER—T. Pinard, Butteville, Or.
 332,455.—KNOB ATTACHMENT—Wm. B. Smith, S. F.
 332,685.—DYNAMO ELECTRIC MACHINE—F. G. Waterhouse, Sac.
 332,467.—ELECTRIC BELT—Chas. N. West, S. F.
 332,470.—AUTOMATIC FANNING MILL—H. S. Zink, Sac.
 332,366.—DRAFT YOKE OR BAR FOR DOUBLE TEAMS—Stockton & Phelps, San Jose, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. American and Foreign patents obtained, and all patent business for Pacific Coast inventors transacted with perfect security and in the shortest possible time.

California Petroleum.

The California petroleum deposits which have been largely developed of late years, are now attracting considerable attention East. Capt. Wallace Moore, of Pittsburgh, Pa., an old-time operator, who recently visited this coast, speaks of our oil industry as follows: "I visited the California oil field while away. The operators have got hold of valuable territory. In the Coast Range mountains it covers an area of 200 miles. It costs twice as much to sink a well 1000 feet as it does in Pennsylvania, but a 50 barrel well in California is worth five times as much as a well of the same capacity in Pennsylvania."

Our California wells are gradually but rapidly increasing their production. The following table shows the product of petroleum in California since 1879:

Years.	Barrels.
1879.....	13,543
1880.....	40,552
1881.....	99,882
1882.....	128,636
1883.....	142,557
1884.....	252,600

The statistics of 1885 have not yet been compiled, but it is certain that a further marked increase will be shown. In the past this State has depended largely upon importations for our supply. It formerly all came by sea, but afterwards much of it by rail. Between 1864 and 1883, we imported 35,682 barrels and 3,605,124 cases, equal to 1,752,408 barrels, of 42 gallons each. We now make a great deal of the oil consumed at home, from our home product. The wells are being opened in all directions, and the petroleum industry is becoming one of the most important ones in Southern California. At the extensive refineries in Alameda county most of the product is manufactured, but the facilities for this purpose will gradually be increased with the increase of product of crude petroleum.

THE Virginia Chronicle says: It is rumored that a smelting furnace will be erected at Reno next spring, to reduce the extensive deposits of carbonate ore in Washoe county and the refractory ores of the Comstock lode, providing Congress does not pass any law to further depreciate the value of silver.

PRACTICAL HYDRAULICS.

NUMBER 10.

PRINCIPLES OF HYDRAULICS.

[Written for MINING AND SCIENTIFIC PRESS by P. M. RANDALL.]
[COPYRIGHTED.]

Ex. 49.—A rectangular orifice being 1 foot wide, 6 inches high, and the head 10 feet, what is the coefficient of discharge if the contraction at one end be suppressed?

Cal.—By Table 7, coefficient of perfect contraction for the given head and given orifice is $=.601$.

Part suppressed $=6$ inches $=.5$ feet.

Entire perimeter $=1+1+.5+.5=3$ feet.

Ratio of entire perimeter to part suppressed $=\frac{3}{.5}=6$.
0.143 times this ratio; $0.143 \times 6 = .858$.

Sum of 1 and this product $=1.858$.

This sum, multiplied by .601, the coefficient of perfect contraction, $.601 \times 1.858 = .615$, the coefficient of partial contraction. — *Ans.*

Ex. 50.—A rectangular orifice being 1 foot wide, 6 inches high, and the head 10 feet, what is the coefficient of partial contraction if the contraction at both ends be suppressed?

Cal.—By Table 7, the coefficient of perfect contraction, for the given head and given orifice, is $=.601$.

Part suppressed $6''+6''=12''=1$ foot.

Entire perimeter, $1+1+.5+.5=3$ feet.

Ratio of entire perimeter to part suppressed $=\frac{3}{1}=3$.
0.143 times the ratio; $0.143 \times 3 = .429$.

Sum of 1 and this product $=1.429$.

This sum, multiplied by .601, the coefficient of perfect contraction, $.601 \times 1.429 = .630$, the coefficient of partial contraction. — *Ans.*

.601 \times 1.048 $=$.630, the coefficient of partial contraction. — *Ans.*

TO DETERMINE THE COEFFICIENT OF CONTRACTION FOR A GIVEN ORIFICE AND GIVEN HEAD OF WATER.

Let a = the height of orifice; b = the breadth of orifice; h = head of water.

And let c , c_n , n , p , and x have the same offices as assigned them under the heading, "Partial Contraction;" c_b = the coefficient of contraction due the breadth.

In Table 7, the heights of the orifice vary from 4 feet to 0.125 feet, while the breadth of each orifice is 1 foot. It is evident, if the contraction be suppressed at both ends of any orifice given in Table 7, the contraction due the horizontal lips only, each 1 foot in length, will obtain. Now if the lips be increased any given number of times 1 foot, the contraction will be proportionately increased. This being done, if the contraction due the ends be restored, and the result divided by the length of the elongated orifice, or by the given number of times that the lips were increased in length, the quotient will express the mean contraction due 1 foot breadth of the given orifice.

For an orifice in Table 7, whose height is a , and whose head of water is h , if the contraction of both ends be suppressed, the ratio $n = \frac{p}{a} = \frac{2a}{2+a}$, and the coefficient of partial contraction:

$$c_n = c + \frac{2ax}{2+a} \quad (96)$$

Multiplying both sides of Eq. (96) by b , the breadth of the given orifice, restoring the end contraction, $\frac{2ax}{2+a}$, dividing the result by the breadth b , substituting c_b for left hand member, and reducing,

$$c_b = c \left(1 + \frac{2ax}{2(a+x)} \right) - \frac{2cax}{2b(1+a)} \quad (97)$$

Substituting in (97) the values of $x = 0.143$, and $n = \frac{2a}{2(1+a)}$,

$$c_b = c \left(1 + 0.143n \right) - \frac{0.143cn}{b} \quad (98)$$

Rule 29.—Find, as by Rule 28, the value of the coefficient of partial contraction for an orifice of the given height, 1 foot wide, and having the contraction at both ends suppressed.

From the value so found deduct the quotient arising from dividing 0.143 times the product of the coefficient of perfect contraction, and the ratio of the entire perimeter of the orifice 1 foot wide, to the part suppressed, by the breadth of the given orifice. The remainder will be the coefficient of contraction due the given orifice. Rule 29 is derived from formula (98).

Ex. 51.—A rectangular orifice being 5 feet wide, 3

inches high, and the head of water 3 feet, what is the coefficient of contraction?

Cal.—By Table 9, the coefficient of perfect contraction, for an orifice 1 foot wide, 3 inches high, under a head of 3 feet, is $=.607$.

Part suppressed $=3''+3''=6''=.5$ feet.

Entire perimeter $=1+1+.5+.5=2.5$ feet.

Ratio of entire perimeter to part suppressed $=\frac{2.5}{.5}=5$.
0.143 times this ratio; $0.143 \times 5 = .715$.

Sum of 1 and this product $=1.715$.

This sum, multiplied by .607, the coefficient of perfect contraction, gives the value of the coefficient of partial contraction, when the contraction of both ends is suppressed,

$$c_n = 1.0286 \times .607 = .6244.$$

By Rule 29, 0.143 times the product of the coefficient of perfect contraction, and the ratio of the entire perimeter of the orifice 1 foot wide, to the part suppressed, divided by the breadth of the given orifice, $0.143 \times 2 \times .607 \div 5 = .0035$,

$$c_b = .6244 - .0035 = .621. — \text{Ans.}$$

Ex. 52.—A rectangular orifice being 2 feet wide, 4 feet high, and under a head on center of 2.5 feet, what is the coefficient of discharge?

Cal.—By Table 7, the coefficient of perfect contraction, as determined by experiment, for an orifice 1 foot wide, and otherwise conforming to the given conditions, is $=.629$.

Part suppressed (both ends) $4+4=8$ feet.

Entire perimeter, $1+1+8=10$ feet.

Ratio of entire perimeter to part suppressed $=\frac{10}{8}=1.25$.
0.143 times this ratio; $0.143 \times 1.25 = .179$.

Sum of 1 and this product $=1.179$.

This sum multiplied by .629: $1.179 \times .629 = .701$.

By Rule 29, 0.143 times the product of the coefficient of perfect contraction, and the ratio of the entire perimeter of the orifice 1 foot wide, to the part suppressed, divided by the breadth of the given orifice; $0.143 \times 8 \times .629 \div 2 = 0.036$,

$$c_b = .701 - .036 = .665. — \text{Ans.}$$

Formulas (95) and (98), and Rules 28 and 29, based upon the mean results of the experiments of Bidone and Weisbach, give but approximations to the true coefficients sought. They are, however, sufficiently accurate, for most cases, occurring in practice. Example 52 is an extreme case. Yet the coefficient .665, determined from its solution, seems practically correct, or not too large, in presence of the fact that the area of the given orifice is twice as great as that of the tabulated orifice whose coefficient of discharge is .629; while the perimeter or contracting boundary of the former is to that of the latter as 12 is to 10. Still it is to be admitted that, in determining the coefficient for a given orifice, the result is more satisfactory when the height of the tabulated orifice employed does not much exceed its breadth.

IMPERFECT CONTRACTION.

FIG. 16.

In the flow of a stream from an orifice, the head of water being nominally still, and the orifice small, in relation to the side of the vessel in which it lies, the contraction is called perfect; the water arriving with considerable velocity at the orifice, as through a conduit, A G F E, Fig. 16, which cross section varies from 1 to 20 times that of the orifice, the contraction thence is termed imperfect.

Let c = coefficient of perfect contraction; c_n = coefficient of imperfect contraction; n = ratio of the cross section of the conduit, A G F E, Fig. 16, through A E, to the area of the orifice O; A = area of orifice; A_c = area cross section of conduit.

The values of imperfect contraction given by Weisbach, as determined by his experiments and calculations, are:

1st.—For circular orifices:

$$c_n = c [1 + 0.04564 (14.821^n - 1)] \quad (99)$$

2d.—For rectangular orifices:

$$c_n = c [1 + 0.76 (9^n - 1)] \quad (100)$$

Equation (99) for circular orifices is readily resolved into this form:

$$\frac{c_n - c}{c} = 0.04564 (14.821^n - 1), \quad (101)$$

And equation for rectangular orifices into this:

$$\frac{c_n - c}{c} = 0.076 (9^n - 1). \quad (102)$$

The length of the conduit or adjunct is assumed to be three times its diameter, or not sufficiently great for the flow of water to be sensibly affected by side friction, as occurs in long pipes.

By giving fractional values to $n = \frac{A}{A_c}$, or values not greater than 1, numerical values corresponding, are found for the expression $\frac{c_n - c}{c}$ in equations (101) and (102).

In illustration: assume the areas of the orifice equal to 1 square foot, and the area of the cross section of the conduit, A G F E, equal to 2 square feet; then $n = \frac{A}{A_c} = \frac{1}{2}$.

Substituting the value of n in Eq. 102,

$$\frac{c_n - c}{c} = 0.076 (9^{\frac{1}{2}} - 1). \quad (103)$$

Now the $\frac{1}{2}$ power of 9, in other words the square root of 9 $= 3$; $3 - 1 = 2$; hence $\frac{c_n - c}{c} = 0.076 \times 2 = .152$, correction found for $n = \frac{1}{2} = 0.5$, in Table 2.

In the computation of Tables 10 and 11, different values from $n = .05$ —the common difference being .05—to $n = 1$, are employed.

TABLE 10.

Corrections of the Coefficients of Flow for Circular Orifices. Weisbach.

$n \dots$	0.05	0.10	0.15	0.20	0.25	0.30	0.35	0.40	0.45	0.50
$\frac{c_n - c}{c}$	0.007	0.014	0.023	0.034	0.045	0.059	0.075	0.092	0.112	0.134
$n \dots$	0.55	0.60	0.65	0.70	0.75	0.80	0.85	0.90	0.95	1.00
$\frac{c_n - c}{c}$	0.161	0.189	0.223	0.260	0.303	0.351	0.408	0.471	0.546	0.613

If n has any value not found in Table 10 or Table 11, substitute such value in equation 99 in case the given orifice is circular, or in equation (100) in case the orifice is rectangular, and solve by means of logarithms.

TABLE 11.

Corrections of the Coefficients of Flow for Rectangular Orifices.—Weisbach.

$n \dots$	0.05	0.10	0.15	0.20	0.25	0.30	0.35	0.40	0.45	0.50
$\frac{c_n - c}{c}$	0.009	0.019	0.030	0.042	0.056	0.071	0.088	0.107	0.128	0.152
$n \dots$	0.55	0.60	0.65	0.70	0.75	0.80	0.85	0.90	0.95	1.00
$\frac{c_n - c}{c}$	0.178	0.208	0.241	0.278	0.319	0.365	0.416	0.473	0.537	0.608

EXAMPLES AND CALCULATIONS ILLUSTRATING THE TABLES 10 AND 11.

Ex. 53.—The diameter of a circular orifice being 6 inches $=.5$ feet, the head on center 9.06 feet, the area of the orifice one-fourth (.25), that of the cross section of the conduit A G F E, Fig. 16, what is the coefficient of discharge?

Cal.—By Table 9, the coefficient of discharge through a circular orifice 6 inches diameter $=.5$ feet in a thin partition under a head of 9.06 feet of water, nominally still, as observed by Gen. Ellis, is $=.60191$; say $c = .602$.

By Table 10, the value corresponding to $n = .25$, the given ratio, is:

$$\frac{c_n - c}{c} = 0.045,$$

Solving this equation for c_n ,

$$c_n = 1.045c.$$

Substituting the value of $c = .602$ in the last equation, there results:

$$c_n = 1.045 \times .602 = .629. — \text{Ans.}$$

ENGINEERING NOTES.

The Davis Island Dam at Pittsburg.

One of the most important engineering enterprises successfully accomplished during the current year is the completion of the Davis Island dam, five miles below Pittsburg, Pa., to secure the uninterrupted navigation of the Ohio river up to that important shipping point.

The dam was formally opened October 8th. The general idea of the system is the conception of a French engineer, Chanoine, from whom the system takes its name. It has been in successful operation for more than 20 years on several streams in France. In the building of a dam on the Ohio river, however, many problems arose that had never presented themselves in France; nevertheless, the question was largely a matter of experience, with the weight of judgment largely in favor of its success. Captain Mahan, acting under the orders of Colonel Merrill, was placed in charge of the work. Its cost has been about \$900,000; but had it not have been for certain unnecessary hindrances, growing out of the tardy action of Congressional applications, it might have been built for about two-thirds of the sum.

It is impossible to give any very intelligent description of the work without elaborate diagrams. Suffice it for the present to say that the dam's distinctive feature is its movability. It is in reality 300 little dams, each so hinged that it can lie prone upon the river bed. This line of movable dams, or "wickets," extends the entire distance across the river, 1223 feet. Of this distance, 559 feet only is the navigable pass or pathway for all craft when the lock is not used. The rest of the dam is designated as "weirs," of which there are three, divided by solid piers of masonry. To raise the wickets of the navigable pass, a "maneuvering boat" is used; to raise the "weir" wickets, a "surface bridge" is called into play.

Like the wickets, this bridge lies upon the bed of the river when not in use, and is raised and joined section by section. To raise the wickets and tilt them into position, where they are retained by a prop, calls into play an ingenious device, the Pasqueau "harrier." A deft pull upon the prop dislodges it, and permits the wicket to recline upon the bed wrested from the river. Between each wicket is a space of an inch or two which can be batted if desired, but which will probably be left open to permit the passage of surplus water.

The monster gates of the lock are closed by force generated in a turbine wheel fed by water stored in huge tanks. Each gate rolls upon its track, and when in position they form the upper and lower extremes of a lock 110 feet wide and 600 feet long; a space sufficient to accommodate a tow boat and average tow of canal boats and barges. To fill the lock requires but four minutes' time; to empty it, the same.

To the hydraulic engineer, especially this is an interesting work. It is invaluable to the industries of Pittsburg, as it keeps up the year round, a competitive means of transportation to the west with the railroads. When the stage of water does not require its use, it lays prone upon the bed of the stream, and the boats pass over it.

Thus far the dam has answered all that could be expected from it, and if the same degree of success continues through the low water season of the river, other improvements of a like nature will be set on foot, wherever practicable in all localities where the demands of commerce may call for the same.

A NEW RAILWAY CABLE DEVICE.—The directors of the Brooklyn City Railroad Co. have under consideration a plan for using a cable for the motive power of surface cars in Fulton street. President Hazard recommends the adoption of a system of twin cables, a few inches apart and joined to each other by steel bars at short intervals. These will make a sort of endless chain of the cable, and the grip wheel will have projecting cogs, so as to revolve with the cable when the car is stopped, and to draw the car when the motion of the wheel is stopped by a brake.

A SYSTEM OF AUTOMATIC BRAKES has been patented in England in which the weight of the cars sets the brakes. When it is required to move the train this weight is lifted from the brake blocks by hydraulic or other power, a set of pistons being attached to each car. It is claimed that with this system the breaking or retarding force is exactly proportioned to the momentum weight of the car, as an empty car will exert less force upon the brake blocks than a loaded one. An automatic regulator is also a part of the system by which the braking force is controlled to prevent "skidding" or sliding.

THE NEW BRUNSWICK SUB-SEA TUNNEL.—Notice has been given that an application will be made to the Dominion Parliament for authority to construct a submarine tunnel under the Northumberland straits to connect New Brunswick with Prince Edward's Island.

ARSENIC IN THE SOIL.—A German writer, in an article published in the *Comptes Rendus*, on June 2d, on arsenic in the soil of cemeteries, from a toxicological point of view, confirms the observation of Orfila in 1847, and proves the possibility of arsenic being conveyed by the soil into a corpse.

USEFUL INFORMATION.

TO PREVENT THE TARNISHING OF SILVER PLATE.—Many efforts have been made to devise a method of preventing the tarnishing of silver and silver-plated ware upon exposure to the atmosphere. The blackening which such articles speedily suffer is due principally to the formation of a superficial film of silver sulphide by the action of the sulphurous vapors in the atmosphere, especially in cities where the large consumption of coal and coal gas charges the atmosphere with sulphur and sulphur compounds. Of all the suggestions that have been made, none appear to have given as satisfactory results as a varnish of collodion—a solution of gun-cotton in a mixture of alcohol and ether. All other varnishes appear to impart a yellowish tinge to the silver or plated wares, but collodion varnish is quite colorless. The articles should be carefully brushed with the varnish with an elastic brush, making sure that the entire surface is covered. The film of collodion will protect the underlying metal surface for a long time. Where silver plate is laid aside and not often used, a prepared cloth or paper is sometimes used as a wrapper, which, if carefully placed around the article, will prevent, or at least greatly retard the tarnishing. These protective wrappers are easily prepared and at small expense. Caustic soda is dissolved in water until the hydrometer shows 20° Beaume. To this mixture is added oxide of zinc until the amount reaches about two-thirds the quantity of caustic soda, and the mixture is boiled until perfect solution is effected. Water is then added gradually to reduce the solution to 10° Beaume. Into this solution muslin or paper is dipped, and when dry is ready for use.

POSSIBLY POISONOUS LARD OIL.—A correspondent of the *Scientific American*, writes that journal from Syracuse, N. Y., as follows: A recent experiment with what is termed low grade lard oil, or bolt oil, has convinced me that machinists and others cannot be too careful to keep it from any slight abrasion of the skin, as the following will prove. Having to fit some new dies to my bolt cutter, and testing their operation, my hands became covered with this so-called lard oil. A slight and almost unnoticed abrasion of the skin below the nail of my left thumb allowed it to come in contact with the flesh beneath; in about an hour it became, first red and painful, then tumid, and finally black, showing unmistakable signs of blood poisoning, which resisted all remedies until cauterized with caustic potash.

Upon this becoming partially healed, I returned to my experiments, having taken the precaution to well protect the injured part by wrappings; but some of the oil found entrance under the edge, and remained in contact with the skin all day, the consequence of which was that the animal poison was again absorbed by the sound but tender skin, and became diffused all over the thumb and as far as the wrist. It could only be checked by further cauterization and poulticing, bathing the wrist and arm with iodine and aconite, and at every renewal of poultices bathing the broken skin with a tepid weak solution of carbolic acid, viz., three drops saturated solution (20 per cent water to crystals) to 1 pint of soft water. The skin has separated from nail to wrist, and after intense suffering for two weeks is slowly healing under a covering of old linen dipped in "cosmoline." Query: Was this oil made from the fat of diseased animals, that is, "honeyard oil"?

PHOSPHORESCENT BEEF.—A gentleman in New York, a few days ago, became greatly alarmed at finding a choice piece of beef, which he had purchased for his Sunday dinner, emitting light when placed in the dark. He sent it to Dr. Edson, of the Board of Health, for examination. Dr. Edson called in the meat inspectors and they shook their sides with mirth because a man had given away an extra fine tenderloin roast. "Why," said one of the inspectors, "when a piece of beef has been kept in an ice box just long enough to be fit for the oven it has a phosphorescent coating which gives out a faint glow in the dark. That is one of the sweetest and tenderest chunks of meat that I ever saw." Dr. Edson sent the beef to his own house, with orders to have it cooked for dinner. He told his assistants the next day that he had enjoyed dining at Colonel Jussen's expense, and had written to the purchaser that the beef was prime.

SUBSTITUTE FOR BUFFALO HIDES.—Since the buffalo has been undergoing its recent rapid process of extermination, substitutes for the old-time buffalo robe are eagerly sought for. The Russian dog skin for a while came into high favor; but of late that has been thrown aside for the hide of the Galloway cattle, which, aside from the unsightly effects of the branding iron, is said to be nearly equal in appearance and service to the far-famed buffalo hide. The two animals have also a striking resemblance to each other in life, and have an advantage over the buffalo in color and texture of fur.

LEATHER AND RUBBER BELTS.—In putting on leather belts always place the rivet head side to the pulley, and for rubber belts place the seam side out or away from the pulleys. Never put resin on a rubber belt. If it is a new one, it will cause the rubber to stick and accumulate on the pulleys, and eventually ruin

the belt, and further, when resin has been applied for some time it will form a glazed, hard surface, causing the belt to slip out more than it did before the application was made. If a leather belt gets too dry, use tallow, or a mixture of castor oil and tallow. Watch the lacings closely, and when you find one giving way replace it immediately.

SAVING FROM SOAP WASTE.—According to Professor Lunge, about 55 to 60 per cent of the fatty acid originally contained in the soap are now recovered in the Swiss works out of the waste soap liquors, which, in former time, were allowed to run away without utilization. The waste soap baths are treated with sulphuric acid, when a pasty precipitate is formed consisting of the fatty acids, pigments, and nitrogenous products. It is decanted, and then the paste is placed at once in a Winterthur separation machine. The water is first of all pressed out, then the pressure is increased while the heat is applied at the same time, finally the remaining mass is extracted with bisulphide of carbon or petroleum spirit. The fatty acids obtained are of good appearance, and, of course, can be used again in the manufacture of soap. There is a large amount of valuable material allowed to pass off with the waste waters of our California works.

HOW WATCHES ARE DEMAGNETIZED.—A watch which has been often brought in near contact with a "dynamo" is very likely to have its steel parts become magnetized to such an extent as to be useless as a timekeeper. It was a long time before any method could be devised to remove the trouble. But it is said that watches are now readily demagnetized by the following simple method: Suspend the watch by a cord or chain in a powerful magnetic field—as in proximity to the pole pieces of a dynamo-electro machine—twisting the cord between the fingers to cause the watch to rotate rapidly, and at the same time gradually move it away from the magnetic influence. By this simple means—the rapid reversal of magnetization and its weakening by gradual withdrawal—the parts become demagnetized.

A WELDING HEAT.—A correspondent of the *Blacksmith and Wheelwright* writes to that journal as follows: I would like to suggest to blacksmiths that they use anvil dust as a flux in welding oblique tires. The result will be likely to surprise those who have never tried it.

COLOR IN PHOTOGRAPHY.—It is said that the medium mulatto makes the finest photograph in the world.

GOOD HEALTH.

An Over-Susceptible Stomach Not Such a Bad Thing to Have After All.

How very powerful a human stomach may sometimes be, and how large a task in the way of digestion it may sometimes perform without complaint, is known to those who have had the opportunity of observing what certain persons with exceptional power are accustomed to take as food, and do take for a long time apparently with impunity, remarks Sir H. Thompson, in the *Nineteenth Century*. But these are stomachs endowed with great extraordinary energy, and woe be to the individual with a digestive apparatus of moderate power who attempts to emulate the performance of a neighbor at table who, perchance, may be furnished with such an effective digestive apparatus!

But, after all, let not the weaker man grieve overmuch at the uneven lot which seems to have been provided for mortals here below in regard to this function of digestion. There is a compensation for him which he has not considered, or perhaps even heard of, although he is so moderately endowed with peptic force. A delicate stomach which can just do needful work for the system and no more, by necessity performs the function of a careful door porter at the entrance to the system, and like a jealous guardian inspects with discernment all who aspire to enter the interior, rejecting the unfit and unbidden, and all the common herd.

On the other hand, a stomach with superfluous power, of whom its master boastfully declares that it can "digest tenpenny nails," and that he is unaccustomed to consult its likes and dislikes, if it have any, is like a careless hall porter who admits all comers, every pretender, and among the motley visitors many whose presence is damaging to the interior. These powerful feeders after a time suffer from the unexpended surplus, and pay for their hardy temerity in becoming amenable to penalty, often suddenly declared by the onset of some serious attack, demanding complete change in regimen, a condition more or less grave. On the other hand the owner of the delicate stomach, a man perhaps with a habit frequently complaining of slight troubles and always careful, will probably in the race of life, as regards the preceding pilgrim, take the place of the tortoise against the hare. It is an old proverb that "the creaking wheel lasts longest," and one that is true as regards a not powerful but nevertheless healthy stomach which is carefully treated by its owner, to whom this fact may be acceptable as a small consolation for the possession of a delicate organ.

For it is a kind of a stomach which not seldom

accompanies a fine organization. The difference is central, not local—a difference in the nervous system chiefly; the impressionable mental structure, the instrument of strong emotions must necessarily be allied to a stomach to which the supply of nerve-power for digestion is sometimes temporarily deficient and always perhaps capricious. There are more sources than one of compensation to the owner of an active, impressionable brain, with a susceptible stomach, possessing only moderate digestive capabilities—sources altogether beyond the imagination of many a coarse feeder and capable digester.

SUGGESTIONS FOR WINTER.—The maintenance of good health is always of first importance to insure success in any undertaking. Suggestions to this end are now especially seasonable. The statistics of mortality show a heavy increase in the death rate every year on the approach of cold weather, and this curiously holds true of the deaths by what are popularly known as summer diseases. When the outside temperature falls the animal heat is lessened, and this decreases the ability of the digestive and other internal organs to fulfill their usual functions. Warmth is life. Cold is death. There is a widespread popular delusion that cold weather, and especially cold winters, are mostly healthful. For the man who keeps himself warm it matters little how the outside temperature may go. There is perhaps an advantage to those disposed to consumption in any healthy cold air, provided always the temperature of the body is maintained by plentiful food and warm clothing. Cold air expands in the lungs, and thus expands them. It furnishes a greater supply of oxygen than warm air does or can. Yet so sensitive is the consumptive to the cold air surrounding his body, that the approach of cold weather is always considered a critical time for him. It ought not to be so, and would not be so, if the temperature of the body was maintained by sufficient clothing.

CONTAMINATED DRINKING WATER.—Contaminated drinking water is the cause of so much sickness that every man and woman grown should know good water when they see it, and have the means of testing it. Water may to all appearance be clear and sparkling and yet contain the germs of foul diseases. The presence of chlorine tells the story. This substance is never found in the soil, and when discovered in water must have come from the human system. In our daily food we use salt—the chloride of sodium. After passing from the human body it becomes separated, and the chlorine makes its appearance in the contaminated water. As much as thirty or forty grains to the gallon is often found in water drawn from wells near where people live. Let it be understood—the more chlorine in the water the more danger, and, also, that no water is really fit to drink which has any of this foreign substance. This is not a pleasant subject to discuss, but people who are too dainty to pay attention to it endanger their health and that of the community they live in. —*Iron Review*.

THE SOIL AS A FILTER.—The conclusions from experiments made by the National Board of Health of New York, and conducted by Raphael Pumpelly, corroborate the opinion of every sanitarian in this country, that though natural soil is an excellent filter for impure air that may pass through it, it is a poor filter for infected water. The experimenters say: "From these results it appears that sand interposes absolutely no barrier between wells and the bacterial infection from cesspools, cemeteries, etc., lying even at great distances in the lower wet stratum of sand. And it appears probable that a dry gravel or possibly a dry very coarse sand interposes no barrier to the free entrance into houses built upon them of these organisms, which swarm in the ground air around leaky drains," etc. Other experiments have shown that ground air will take up infectious germs from water that is disturbed.

Water is Fattening.—It has been observed that water is fattening, that those who drink large quantities of water have a tendency to fullness and rotundity. That there is considerable truth in this observation the *Medical and Surgical Reporter* fully substantiates. That excessive inhibition of very cold (iced) water (especially when one is very warm) is not to be commended, yet we have reason to believe that the unlimited use of pure spring water, at its natural temperature, is not only very conducive to health, but has an actual tendency to favor a fullness and roundness of body. Whether this is the result of a better action on the part of the digestive, assimilative, and depurative functions, owing to the internal cleanliness or flushing of the human sewers produced by large quantities of water, or whether water has some specific action in producing this fullness, we do not know, neither does it signify, since observation confirms as a fact that the free use of water does have this effect.

FALLING OFF OF HAIR.—R. P. Henderson advises in the *Herald of Health*, use directly on the scalp every night before retiring, a preparation of one part of crude white birch oil and five parts of alcohol; the latter will evaporate at once, leaving the oil on the scalp. Do not use too much. Follow up the treatment about six weeks, then discontinue; go bare-headed all you can; use a light, well ventilated hat when you must wear one; cut the hair short; invigorate your health by living more out of doors.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

CON, AMADOR.—*Sentinel*, Dec. 16: There is talk that the old shaft of the Con. Amador mine of Sutter will be opened soon, in the belief that the mine can be made to pay through the old works. The Mahoney is working a surface lead with some degree of success. Periodically the owners of this mine come up from the city, walk around the town, take a look at the mine, and assume an air of mystery, which causes the Sutter Creek people to remark, things are going to boom sure this time. They are still hoping. Sam Stewart is crushing rock from a surface lead on the Lincoln ground, which runs toward the Mahoney. Mr. Knight is having a rigging put in at the Zelle mill to enable him to test his water wheels, and there is talk that Pelton will put in a wheel here and have a public test of the merits of the two wheels. We have heard it suggested that if the Kennedy mine should be worked successfully that fact might induce the starting up of the Oneida. The Mahoney mill was shut down Monday and the water is being pumped out of the mine for the purpose of letting the parties who have been talking of buying see it.

MOORE.—Amador *Ledger*, Dec 16: This mine continues to develop finely. The shaft is down over 300 feet. The ledge is reported over 10 feet wide; nearly the whole of it of paying grade, and four feet of it is exceedingly rich, showing free gold to the naked eye in abundance. It is confidently asserted that this ore will yield from \$30 to \$40 per ton. The prospects are so encouraging that the 10-stamp mill is to be put in repair and started up as soon as possible. D. Donnelly of Sutter Creek was over Wednesday last in consultation with W. A. Nevills regarding the overhauling of the mill.

DOYLE.—William Doyle, the owner of the quartz mine in Hunts gulch which bears his name, has just finished a test crushing of ore from his claim at the Kelly mill. He took 25 tons of ore from the dump, which he considered of average quality. The rock yielded \$6 per ton in free gold. The sulphurets, of which the ore carries from 2 to 3 per cent, were not saved. And as the assay value of the sulphurets runs over \$500 per ton, the rock, including sulphurets ought to yield from \$7 to \$8 a ton. The ore body is of vast dimensions, and the result of the test is of such an encouraging character that the mine is well worthy the attention of capitalists on the lookout for profitable investments. Doyle is a poor man, and conscious of his inability to operate a mine such as his. The whole or a portion of the claim may be secured on very liberal terms.

MISCELLANEOUS.—The South Spring Hill mill is now running steadily to its full capacity of 20 stamps. Everything runs smoothly and satisfactorily. It is one of the finest mills in the county. A clean-up at the Gover mine was made last week—the first since the resumption of work. We are not able to give the yield per ton, further than that it reached a paying figure. The ore is low-grade, but sufficient to pay something over expenses. At the Loyal Lead mine north of the Gover, affairs have a prosperous look. The ledge, we are told, is 30 feet wide, and of good quality. The big tunnel at Middle Bar has now reached a total length of 3200 feet. Small stringers of quartz are frequently met with, and occasionally bunches of rich black metal. The header is yet 200 feet from the spot where the rich deposits of the Mammoth mine are likely to be met with. W. A. Nevills & Co., completed the purchase of the Moore mine on Wednesday, paying the balance of the purchase money of \$15,000. The bond did not expire until spring, but the prospects of the mine are so flattering that they deemed it advisable to redeem it at once.

Mariposa.

DILTZ MINE.—*Mariposa Gazette*, Dec. 16: Captain Diltz says the rainy season stopped so short that it did him but little good. But when there is no water to wash he continues excavating and wheeling out from the large crosscut, which is 40 feet wide and from 15 to 50 feet deep. This crosscut passes through numerous strata of quartz, each of which are inlaid with a casing of red ochre, decomposed quartz and dirt, which principally carries the gold that is saved from the wash. Free gold is frequently observed and occasionally a small nugget is picked out, but the whole mass is taken to the front, assorted and piled. The hard quartz is piled for milling. The decomposed quartz and casing, which carries the free gold, is piled to itself and the great mass of dirt and vein matter is put in another pile, which makes three heaps in all.

Nevada.

FINE PROSPECT.—*Foothill Tidings*, Dec. 18: This morning Hank J. Snow took about half a pound of rock from a quartz ledge which he owns and which is situated on Deer creek, pounded up the rock in a hand mortar and the result was a yield of about 98 cents in gold and some sulphurets. The ledge is large, and the rock pounded up was just taken from the croppings.

Placer.

CLEANUP.—Placer Co., *Republican*, Dec. 16: Last Saturday was pay-day at the Big Oak Tree mine at Colfax. The pay-roll aggregated \$6,000, \$15,000 was cleaned up for the first run, and the miners who work there say the quartz continues as good as ever. The French company has bonded the Forks House Consolidated, the Cape Horn, and the Alameda Consolidated claims between Damascus and Indian Springs. They have also entered into an arrangement to purchase the Mountain Gate mine at Damascus on payment of a certain percentage of the stipulated price. The prospects of the Palmer & Floyd tunnel, down Auburn ravine, are more encouraging every day. The rock found so far is rich both in gold and silver. They are at present at work on a winze. Two assays of the rock have been made, one yielding \$50 in silver and \$19 in gold, the other, of selected rock, yielding \$600 in silver and \$15 in gold. The mine has been named the St. Anthony.

DEBRIS DAM.—The dam constructed on Bear river to restrain the debris from the Liberty Hill mine has stood through the late storms, and is pronounced by competent miners as very satisfactory.

Shasta.

DEADWOOD AND FRENCH GULCH.—*Redding Independent*, Dec. 16: There is considerable mining going on in the gulches between Shasta and Deadwood. It was pay-day Sunday for the employees of the Niagara mine, owned by W. T. Coleman. T. Plumb, one of the leading merchants of that place, informed us that over \$3400 was distributed among the boys. Tom Green employs over 20 men in his mine, and he informed us that he is taking out some very rich rock at present. The Scorpion mine is running full-handed and the returns from the ore are good. The McDonald boys are taking out some splendid ore at their mine near Deadwood, and the deeper they go down the richer it gets. Chinamen own and run all the large placer claims in and about French Gulch. They have several Giant monitors in operation, and the farmers along the Sacramento river never make any pretensions to serve an injunction on their claims.

San Bernardino.

SODA LAKE ITEMS.—*Calico Print*, Dec. 20: Last Thursday Mr. H. B. Stevens returned from Soda Lake, where he has been prospecting and attending to his mining interests. He says he is very favorably impressed with the prospects of that section, and considers it a good mineral country, but it will require time and hard work to determine whether the mines will be permanent. New ore deposits are being discovered every day, and it is expected that considerable work will be accomplished after the first of January. Two districts have been organized, the Sullivan camp being included in what is now called Five Points district, and Riggs' camp in Solo district. The last name is very inappropriate, and the public may think it was chosen by a singing school class. The name of Soda Lake is more appropriate, because it has always been associated with that section by the public. We understand that the organization of the "Solo" district is not complete, and we suggest that the old name of Soda Lake be retained, unless the reasons for the change are conclusive. H. E. Evans' well in the Riggs camp is now down 40 feet, and he expects, according to the "water witch," which has directed him to water several times, to reach water at a depth of 65 feet. Mr. Stevens was informed by the owner of the gold mine, near Cadiz, that he had sold the same to a San Francisco capitalist, and in due course of time a mill would be erected there. This is the mine that J. L. Porter, of Waterman, had bonded and spent about \$12,000 in developments. Mr. Stevens intends in a few weeks to do some work at his mines near Bagdad.

Sierra.

CLEANUP.—*Mountain Messenger*, Dec. 19: The cleanup at the Bald Mt. Extension, last Sunday, at Forest City, was 199½ ounces of gold. The miners over north have a good flow of water, and are busy at work in their claims. Aaron Todd last week cleaned up 20 ounces of gold at his drift claim in Fotosi. The Forbes & Taylor mill is crushing ore at the Belmont ledge, Poker Flat, with good results. The Union Gold Mining Co., at Gibsonville, is having large weekly yields of gold. David McDonald, Thos. Castello and Wm. Cosker, of Howland Flat, called on us Thursday, and reported snow two and a half ft. deep in that mining camp; no snow at Poker Flat; two ft. at Deadwood; two and a half ft. at Fir Cap.

FOREST CITY.—Evans Johns and Wm. Feezy have taken the contract for running 326 ft. of sluice tunnel for the Extension Co. Mike Wylie and Bert Bradbury have a contract of 800 ft. of tunnel to run for the South Fork, and have already commenced operations. The company have put up a fine building to be used as a carpenter shop, blacksmith shop and timber shed.

Tuolumne.

MINE SOLD.—*Union Democrat*, Dec. 19: The Hyde mine and ranch property has been sold to A. P. Hotaling, Henry Allen and John W. C. Maxwell. A bond was placed in the Recorder's office Wednesday to the effect that M. H. Hyde will give a clear title upon compliance with an agreement on the part of the purchasers, and the final payment of \$16,000 a year hence. In the meantime the mine will be worked by the new parties. It has been regarded as a valuable property, but lack of means has prevented development heretofore. During the year if experts are not mistaken it will make a fine showing among paying mines.

Trinity.

AT WORK.—*Trinity Journal*, Dec. 16: Miners throughout Trinity county are all at work with an ample supply of water; it is stated on authority that more work will be done in hydraulic mines before January 1, 1886, than was done during the entire season of 1884-85. It is further predicted that the gold yield of Trinity for the current season will be greater than ever before known.

BIG PAY.—Newman & Hurlbut made a cleanup in their arastra on Eastman gulch this week, and we learned that the ore crushed averaged \$115 per ton. This is away up, and they have more of the same kind on the dump and in the mine.

NEVADA.

Washoe District.

HALE & NORCROSS.—*Enterprise*, Dec. 19: On the 300 level, the main lateral drift north is steadily advanced, following the diamond drill hole which was sent in a due north and not northeast direction toward the Savage line. This drill hole was about 100 feet in length, reaching to and a little into the Savage mine. It tapped no water and showed no rich sulphurets, and will be steadily continued through to and into the Savage ground, as it can be done with the most perfect facility and safety, after which crosscuts will be made east toward the good ore body developed in driving the diamond drill to the northeast, where the drill demonstrated that water might be found as well as ore. On the 300 level, upraising in the ore body above the deep winze station has attained a height of 40 feet. The ore body has widened out considerably and is showing well. It is not a solid mass of rich ore, but streaks and bunches of it assay up in the hundreds. Some of this ore reminds one of the very rich black sulphuret and chloride ore of bonanza days, when Fair and Mackey and Flood and O'Brien were getting rich tolerably fast. The ore is good enough, and all that is required is plenty of it. It is being stopped out and hoisted to the surface as opportunity offers.

UNION CONSOLIDATED.—On the 500 level the crosscut east, 100 feet south of the Sierra Nevada

line, is in 365 feet; material, favorable, same as last week.

KENTUCK.—The regular milling supply is kept good from the old upper workings, with plenty of ore in sight to last for many months.

BEST AND BELCHER.—On the 1000 level west crosscut No. 3 is in 332 feet; material, vein porphyry, clay and quartz.

MONTE CRISTO.—Ore enough is being extracted to keep the mill steadily running.

Hawthorne District.

THE DICTATOR.—*Walker Lake Bulletin*, Dec. 19: A development was made in the Dictator last week, which will almost immediately place it on the list of paying mines. A large vein of free gold quartz has been uncovered, the assays being from \$30 to \$40. As this is on the large and strong ledge of Hawthorne district, and right at the crest of the slope to the railroad, the value of the discovery can be easily seen. Extraction will be easy and the cost of hauling to the mill at Kinkead will be but light. If there is no sudden change for the worse, Moss will soon have to enlarge his mill.

THE PAMILCO.—The Pamlico mill is still showing ore which is really astonishing in value. Instead of rock, some of the pieces may be described as gold having a little quartz mixed with it. Of course, there is no immense ledge of this kind of material, but a little goes some distance, and the six inches that now show are about as opulent inches as can be found in this part of the country.

ARIZONA.

TO SHIP ORE.—*Prescott Courier*, Dec. 14: Frank Alters proposes to put a blast or two in his Catocin mine and knock down twenty or thirty tons of high grade silver ore which he will ship to Pueblo. His ventures in this line have paid him well. The expense of shipping and treating ore runs, we believe from \$60 to \$100 a ton. Mr. Alters thinks that when the railroad shall be built to Prescott, there will be a profit in shipping ores that assay \$25 a ton. When that time shall have come there will be thousands of miners in the country around Prescott. The Sterling mill is running and paying. The men were paid off a few days ago. B. T. Riggs & Co. have their hydraulic diggings on Lower Lynx creek in good fix, and are praying for a downpour of rain or snow. They have a great many acres of gravel that will pay to pipe. Mr. Tracy, of Hassayampa creek, recently found a piece of gold that weighed an ounce, and another which is worth \$10. He has taken several pounds of nuggets out of his claim and expects to take out twenty times as much. The chlorides of Humburg, Turkey creek and some more districts are hoisting a great deal of rich silver ore and shipping it to various smelters. Miners are anxiously waiting for the erection of sampling works in Prescott. They would be of great convenience, and all our people hope the parties who talk of erecting them will do so as speedily as possible.

COLORADO.

NOTES.—*Colorado Miner*: The last mill-run from the Mint lode returned 180 ounces silver to the ton. Work has been closed down for the winter. The machinery to be placed on the Nyanza lode, on Democrat mountain, is now on the ground, and Capt. McCassey is engaged in placing it in position. Work is now being done on the Surprise lode, on Keith mountain. If a certain project is consummated, a prospecting tunnel will soon be underway at or near the base of Democrat mountain. Report reaches us that a sale has been made of the Virginia lode, in Spring gulch. The Beecher lode, on Democrat mountain, is now being worked with remunerative results. Messrs. George Shavalia and Wm. Perrin have been working the property under lease for a short time. The percentage in silver is small, but in lead it returns handsomely, and with the present price for that metal the lode can be worked profitably.

IDAHO.

WISWELL MILL.—*Wood River Times*, Dec. 16: The Wiswell mill was cleaned up yesterday by Frank Wiswell, General Agent of the Wiswell Electric Machinery Company. The amalgamator in charge of the mill stated that it had run close on to 22 hours, and that 12 to 14 tons of ore had been put through. The result was a ball of hard amalgam weighing about eight ounces, which would yield about two and a half ounces of fine gold. It was locked up to await the next cleanup, which will be made in about one week. J. C. Conklin, who came up from Salt Lake on purpose to see the cleanup, was present. He examined every working part most critically, and with the exception of the gearing, which he thinks, is rather weak from so much effective work, he considers the mill a perfect success. Captain Lusk was also present, as were a number of miners and old millmen, and all pronounced the machine built on correct principles, and evidently capable of doing excellent work. Superintendent Ole Rorem, of the Donovan Company, expressed it as his conviction that the mill would work closer than any gold mill he ever saw, and that it would do the work of 15 stamps. He said that in a short time, the company would doubtless require one or two more.

MONTANA.

SHUT DOWN.—*Inter-Mountain*, Dec. 15: Acting Superintendent Muller, of the Mountain Copper Company, has received peremptory orders to close down the smelters as soon as the ore already taken out has been reduced. Since Sunday no ore has been hoisted from the mines and none will be until orders to the contrary are received. There is only ore enough on hand to keep the works running for about five or six days, which will be the date for closing down. About 150 men will be thrown out of employment. While no more ore will be taken from the mine, the force of miners continues as before, their operations being directed to the development and prospecting work.

LIQUIDATOR.—*Inter-Mountain*, Dec. 16: One hundred tons a day are worked which yield 40 ton of concentrates, running from 22 per cent to 30 per cent. copper. The higher grades of concentrates are shipped direct to Liverpool, while the lower grade is sent to the Bell smelter, where it is reduced to matte and shipped to Liverpool. At present the company are not working their mine, and will not

open it up until the ore on the dump is exhausted. It is also their intention shortly to erect a furnace and smelt their own product. This, however, will not be done until operations are again begun on the mine. The Liquidator mine adjoins Clark's Colusa, and has already proven itself to be a large producer. The vein is from 30 to 50 feet in width, and there is an immense reserve of ore in all the levels which has never yet been touched. With a furnace added to its plant the Liquidator will take rank among the largest and most permanent producers in this district.

The Alice Mining Company own and operate four mines, namely, the Alice, Magna Charta, Valdemere and Rising Star, all on the Rainbow lode. In the Alice the main shaft is down 800, on the Magna Charta 700, and Rising Star 500. The workings in the Alice are from the 600-foot level upward, no ore having been taken from lower points. Their mines produce 100 tons of ore daily of an average value of \$40 a ton.

The Moulton also located on the Rainbow lode is sinking the main shaft to a depth of 700 feet. No ore has been extracted below the 500-foot level. The average value of the ore is \$40 a ton.

The Union Consolidated consists of a group of mines occupying a tract a mile in length and half a mile in width. The company is sinking on mines Nos. 1, 2 and 3. The property is being rapidly developed under the able management of the superintendent, Patrick Clark.

Goldsmith No. 1, the property of Mr. George Tong, is producing a quantity of the richest ore in the camp. The shaft is down to a depth of 265 feet.

The North Star and Salisbury are the most northern mines operated in the district, and are being worked under bond and lease by George Tong. They yield quantities of low-grade free milling ore.

The Black Rock is worked under lease by George Stoner. It produces manganese ore, which is very desirable in all mills, as it readily amalgamates with baser ores. The mine is making good returns to the owners and lessees. The ore averages about 50 ounces to the ton.

The Elm Orlu, owned by Hon. W. A. Clark, produces ore similar to the Black Rock, which is treated at Clark's smelter, and is used to make high-grade silver copper matte. It is one of the profitable mines of the camp.

NEW MEXICO.

MINERAL.—*Socorro Bulletin*, Dec. 16: The Graphic and Georgia Bell are steadily dumping good mineral under the superintendence of Capt. Day, and shipping to the Graphic Mining and Smelting Company of this city. H. G. May has completed a number of assessments, and on Thursday returned to his old camp in Water canyon, where he will commence several mining contracts and also work his own properties. The Graphic M. & S. Co. are working the Greyhound under the eye of Superintendent Day, and ship three carloads of the ore to Socorro per week for treatment. The mineral runs high in lead and gives a good percentage of silver. Work on the Morning Star in the Socorro district will soon be resumed. The tunnel is now in 500 feet, and 225 feet of work will be added by Capt. Day, the superintendent of the property. It is the opinion of the best mining authorities that he will strike ore in place. The May Cooper and White Rock claims, in the Iron Mountain mining district, are dumping mineral, the former from a 100-foot ore body and the latter from a four-foot vein. Arthur Radcliff a few days since discovered and located what will probably prove on development to be one of the most important claims in Water canyon. The discovery is in the north branch of the canyon, and he named it the Mugwump. Just below the surface the vein is eight feet wide and assays 50 ozs. of silver per ton. The mineral bears a great resemblance to that from the Jane Bowman, J. S. Sniffen and R. N. Sniffen have purchased the Rowena mine, in the Pueblo district, from T. M. Holmes. The property has a 110-foot shaft.

OREGON.

PLACERS.—*Jacksonville Times*, Dec. 10: Placer miners want more water at once. Gin Lin has had a full head of water for the past month at his Uniontown diggings and is making the most of it. Messrs. Willis and Gregory, two experienced miners, propose commencing mining operations on Forest creek soon. Supt. Ennis was over to the Sterling mines this week and reports operations progressing finely with plenty of water. John Miller of Farmer's Flat and Logg & McDonnell of Forest creek have already done some pipping, but have not enough water to work continuously. Both have first-class mines, Chas. Kearns has been awarded the contract for hauling 300 tons of quartz from Geo. Schump's ledge in Willow Springs precinct to this place. The hauling will be commenced soon. Tim Smith was up from Galice creek a few days ago. He informs us that quartz mining is about suspended in that camp, but that work on the Yank ledge will probably be resumed in the near future. Since it has become a settled fact that a fine quartz mill will be put up in this place, a great deal more prospecting is being done. Work has been commenced on a number of ledges which have been lying dormant for many years. A Footh creek correspondent writes the *Times* as follows under a late date: All the miners here are ready for water, and the new prospectors of the middle fork of Footh creek have their cabins built, roads dug and reservoirs made, and by the gold they pick up once in a while they feel quite hopeful. Thos. Mee is taking up his flume and relaying another one with better grade. Duffell, Lance & Co. have remodeled their reservoir, with hopes of doing better work this winter. We are informed that Brown & Co. have given orders for the construction of the quartz mill to be put up at this place and the machinery will be on the ground at the earliest possible moment. It will be a first-class mill in every particular, having all the latest improvements and capable of dealing with our rebellious ores in a rapid and efficient manner.

RICH STRIKE.—*Oregon Sentinel*, Dec. 12: Dick Cook, the well known, experienced quartz miner of this section, was sent to Galice creek last week by California capitalists to investigate that region in regard to quartz. On his return he informed us that the Yank ledge was not being worked at present, but tunneling would be resumed before long. While he was there a new strike of immense richness was made in Green Bros' ledge that will surely prove a bonanza to the owners if the new vein holds out as

it now shows. This mine has been successfully worked for many years, but not having the late improvements for saving sulphurates, probably not one-half of the gold was saved.

UTAH.

THE LEACHING WORKS.—Southern Utah Times, Dec. 14: The new leaching works, now almost completed, will begin operations next week. They are situated a mile southwest of town, and the plant, occupying the greater part of the building, is the most perfect of any in the Territory. A brief description of the works and process is of deep interest to our readers. The ore, after passing through a rock breaker, runs down through a hopper to a pair of Cornish rolls 14 inches wide by 18 inches in diameter where it is reduced to pulp fine enough to pass through a twenty-mesh screen where it is received by an elevator and emptied into bins above the leaching tanks. The bins are provided with chutes, so that the tanks may be charged by pressing a lever. The tanks, 10 in number, are 4x10 feet, and are of about ten ton capacity. The pulp is first treated to a bath of sulphate of copper; after standing six hours it is covered with a solution of hyposulphite of soda; six hours more completes the leaching and the second liquor is drawn off and the solvent conducted through pipes to the precipitating pans; these pans have perforated false bottoms above the real bottom, that permits the solvent to escape, but retains the pulp. After the solvent is drawn off, a stream of water under a twenty-foot pressure, is turned into the pans, a valve opening into a sluice at the bottom of each is opened and the tailings are sluiced out. The precipitating pans, three in number, are of considerable capacity. When the solvent is in these pans the sulphate of calcium is added which precipitates the silver in form of sulphides; after doing its work, it runs into a reservoir from which it is pumped back to the solvent tank above the rolls and used again; next is the drying and pressing of the sulphides for market. The entire process requires about eighteen hours. The company has 30,000 tons of tailings on hand. The machinery is run by a forty-horse-power engine. The best of material has been used and the works constructed in a most substantial manner indicating that the projectors of the enterprise, Messrs. G. L. Harding & Co., have an abiding faith in its success. The managers are reticent as to the terms they will offer chlorides but it is their intention to buy the ore they work. We are authorized to say that fifteen-ounce ore can be worked at a profit to the miner, as from sixty to seventy-five tons can be reduced every twenty-four hours.

PACK NOTES.—Record, Dec. 19: The Ontario mill shut down this week to put a patch on the big gear and for other miscellaneous repairs. The Corner Stone, the promising property, owned by Andrew Lundin, located about 600 feet north of the Daly, will have work resumed upon it the beginning of the year. The developments at present consist of an incline shaft 35 feet deep. Good ore has been struck, which carries a fair showing of high-grade yellow chlorides. It will most likely turn out to be a good mine. Some 20 miners were laid off at the Sampson this week on account of the scarcity of ore in the stopes. The large ore body that was struck the latter part of the summer proved to be a large pocket, and it is very nearly all dug out, but the ore in the rest of the mine is still as plentiful as before. This large body was struck and quite a number of men are still working in the stopes. In the east drift a force of men are working contract work, driving the drifts, and another force are at work in the tunnel running a drift to the west as a prospector. The company expect to cut the ledge and drain off the water from the lower levels some time in February. A number of men from the Sampson have left the camp for South Pass, Wyoming, to work on the Carisa mine, at that place.

Please Remit.

We would call the attention of Patrons who have not yet remitted their subscription for 1886 to the fact that we are not only in need of that which is due to date, in making settlements, but can use to great advantage, remittances for the next year, in making improvements and better arrangements for the future.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.
J. J. BARTLETT—Amador and Calaveras Co's.
F. H. HORN—Nevada (State).
G. W. INGALLS—Arizona.
E. L. RICHARDS—San Diego Co.
R. G. HUSTON—Idaho and Montana.
GEO. McDOWELL—Santa Clara and Santa Cruz Co's.
HUGH ELIAS—Nevada Co.
J. WINKLER, Alameda Co.
M. L. DENNY, Yuba and Nevada Co's.
J. B. PATCH, Nevada and Utah.
L. D. CLARK, Tehama and Shasta Co's.

Complimentary Samples.

Persons receiving this paper marked are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time he intends to pay for it, let him not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent. LOOK CAREFULLY AT THE LABEL ON YOUR PAPER.

Mining Share Market.

There is very little of interest going on at present in the mining share market. The working miners on the Comstock are all digging away and developing their claims, in the search for good paying ore. Wherever this is struck the stock market will feel it, but until something definite shows up in that region there is not much chance of improvement in the general market. The bonanza hopes and prospects of the middle mines still hold good, and in fact extra good at the present time, in view of what has been and is being developed in the ore vein or deposit in the upraise above the 3000 level. Sundry rumors of changes in the executive administration of the Yellow Jacket mine, also that the recent 75-cents assessment was levied for the purpose of putting a big new pump into the Yellow Jacket new shaft, to pump out and drain the Gold Hill section of the Comstock, also that the Bullion combination shaft was going to be sunk 700 feet deeper, in order to intercept and assist the drift coming south on the 3000 level of the Potosi ground, were all humbugs.

Bullion Shipments.

Argus, Dec. 16, \$8534; Richmond Con., 16, \$12,485; Oro Grande Mill, 18, \$3271; Koebeig Mill, 18, \$2500; Lexington, 12, \$18,056; Moulton, 12, \$21,760; Alice, 12, \$35,088; Allen Hayes, 12, \$2032; Hanauer, 15, \$6,700; Stormont, 15, \$3350; Queen of the Hills, 15, \$1400; Germania, 16, \$5758; Hanauer, 17, \$7000; Crescent, 17, \$340; Germania, 17, \$2491; Alice, 18, \$6569; Davenport, 18, \$266; Bauner, 16, \$7200; Germania, 20, \$2646; Hanauer, 20, \$4850; Overland, 20, \$1200.

The banks of Salt Lake City report the receipt for the week ending December 16th, inclusive, \$95,256.74 in bullion and \$25,271.36 in ore; total, \$120,528.04.

BOTANY.—Girls and boys will gladly accept one of Muller's pocket microscopes; X'mas gift.

AN EXTRAORDINARY RAZOR

HAS BEEN INVENTED BY THE QUEEN'S OWN COMPANY, of England. The edge and body is so THIN and FLEXIBLE AS NEVER TO REQUIRE GRINDING and hardly ever setting. It glides over the face like a piece of velvet, and is a luxury. It is CREAMING A GREAT EXCITEMENT in Europe among the experts, who pronounce it PERFECT. Two dollars in buffalo handle; \$3 in ivory. Every razor, to be genuine, must bear on the reverse side, the name of NATHAN JOSEPH, 641 Clay street, San Francisco, the only place in the United States where they are obtained. Trade supplied; sent by mail 10c. extra, or C. O. D.

The California Perforating Screen Company.
All kinds of Quartz Screens, shot and brass for zinc, copper and brass for
FLOUR AND OTHER MILLS.
Quartz Mill Screens a Specialty.
147 Beale Street, San Francisco.

HALF SHARE IN GOLD MINE FOR SALE.

Three full claims; one claim developed; 400 feet shaft and tunnels. Mill test 34 tons gave 21 ounces gold, 3 ounces silver per ton; 100 tons gave \$20 gold per ton on ounces and \$23 in tailings; 14 tons gave \$7 per ton on plates. Custom mill within 6 miles of mine. For further particulars apply to
G. W. SPAWORTH,
Lang Station, Cal.

BADGES FOR ALL SOCIETIES,

Police, firemen, etc., presentation prizes or emblems, in gold, silver, or metal, sold at society prices by the agents of the Universal Badge Manufacturing Co., NATHAN JOSEPH & CO., 641 Clay St. Workmen and K. of P. badges in gold, \$1 each, sent C. O. D. Trade supplied

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

Manufacturers of

MINING MACHINERY, ENGINES, BOILERS, Etc.

We are manufacturing from Special Designs of the most experienced and successful Practical and Scientific Experts, Complete Plants for all descriptions of Mining Operations, as follows:

CONCENTRATING MACHINERY—Best and Cheapest, Cornish Rolls, all Steel Wearing Parts, Most Practical Styles of Two, Three and Four Compartment Double and Single Jigs, Sizing Screens, Patent Hydraulic Separators, Tables and Concentrators.

STAMP MILLS for Reduction of Gold and Silver Ores, whether free milling or base. Most useful and substantial styles of Single and Double Discharge Mortars, Wet or Dry Crushing.

STEEL SHOES AND DIES, Tappets and Cams, cheapest and best Blake Improved Rock Crushers and Automatic Ore Feeders, Superior Amalgamating Pans with wood or iron sides.

PANS FOR TREATING GOLD ONLY, Settlers, Clean-Up Pans, Retorts, Furnaces, Dump Cars, Hoisting Machinery, Cages, Landing Dogs, etc.

CORLISS, MEYER'S CUT-OFF AND BALL'S PATENT VALVE Engines of extra strength and durability.

STEEL BOILERS of Two Sheets only, Steel Economic Boilers, combining with the safety, durability and economy of the Stationary Boiler, the convenience and portability of the Portable. It occupies but little space, and is the best and cheapest boiler ever made.

WE ALSO MANUFACTURE SAW MILL MACHINERY.

We are also Sole Agents for the Gordon and Maxwell Steam Pumping Machinery, and carry a full stock of all kinds of Mill Supplies, including the

Albany Lubricating Compound and Oils.

1850. 1885.
RANKIN, BRAYTON & CO.,
BUILDERS OF...
MINING MACHINERY.

San Francisco: 127 First Street. Chicago: 100 N. Clinton. New York: 145 Broadway.

PLANTS FOR GOLD AND SILVER MILLS, embracing machinery of LATEST DESIGN and MOST IMPROVED construction. We offer our customers the BEST RESULTS OF 35 YEARS' EXPERIENCE in this SPECIAL LINE of work, and are PREPARED to furnish from SAN FRANCISCO or CHICAGO, the MOST APPROVED character of MINING AND REDUCTION MACHINERY, adapted to all grades of ores and SUPERIOR to that of any other make, at the LOWEST POSSIBLE PRICES.

We are also prepared to CONSTRUCT and DELIVER in COMPLETE RUNNING ORDER, in any locality, MILLS, CONCENTRATION WORKS, WATER JACKET SMELTING FURNACES, HOISTING WORKS, PUMPING MACHINERY, ETC., ETC., of any DESIRED CAPACITY.

WATER JACKET SMELTING FURNACES

For COPPER and ARGENTIFEROUS LEAD ores of NEW and ORIGINAL DESIGNS, covered by LETTERS PATENT. No other Furnace CAN COMPARE with these for DURABILITY, and in CAPACITY for uninterrupted work. MORE THAN 150 of them are now RUNNING in various parts of THIS COUNTRY, as well as many in FOREIGN COUNTRIES, giving results NEVER BEFORE ATTAINED as regards CONTINUOUS running, ECONOMY of fuel, AMOUNT and QUALITY of BULLION produced. These CLAIMS have been PROVEN BY RESULTS in ANY NUMBER OF INSTANCES, and the GREAT SUPERIORITY of this SYSTEM of smelting ores DEMONSTRATED BEYOND QUESTION. COMPLETE PLANTS furnished to order of any CAPACITY, with ALL IMPROVEMENTS that experience has DEMONSTRATED as VALUABLE in this class of work.

Beyond question the cheapest and most effective machine of the kind now in use adapted to all grades and classes of ores.

This machine has been THOROUGHLY TESTED for the past TWO YEARS, under a GREAT VARIETY OF CONDITIONS, giving most EXTRAORDINARY results FAR IN ADVANCE of anything EVER BEFORE REALIZED. A recent COMPETITIVE TEST at the Carlisle Mine in Mexico, showed an ADVANTAGE OF OVER 30 PER CENT in favor of THE DUNCAN. The amount SAVED OVER THE TRUE being sufficient to PAY THE ENTIRE COST of the machines EVERY MONTH OF THE YEAR. One of its MOST VALUABLE features is as an AMALGAMATOR. It saves all THE AMALGAM GOLD and SILVER that ESCAPES the BATTERIES, PANS or SETTLERS, making the machine worth MORE than ITS COST for THIS PURPOSE ALONE.

Baker's Mining Horse Power.

Possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower, without interfering with a hoisting apparatus. It is made entirely of iron, no piece weighs over 300 pounds. At the ordinary speed of a horse, a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting-drum is under the complete control of the man of the shaft, and is capable of carrying 500 feet of five-eighths steel rope. SEND FOR CIRCULAR.

Manufacturer of all kinds of Chemical Stoneware—FOR—Manufacturing Chemists. Also Chemical Brick for Glover Tower.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE: FIVE HUNDRED AND SEVENTY-FIVE DOLLARS.
(\$575 00), F. O. B.

OVER 1,000 ARE NOW IN USE. Saves from 40 to 100 per cent more than any other Concentrator. Concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the Fulton Iron Works, No. 230 Fremont Street, San Francisco.

As the result of a suit East against an End-Shake Machine (the Embrey), similar to the Triumph, the Frue Vanning Machine Company owns the Embrey patent, and can put in the market an End-Shake Machine of earlier patent that will do as good work as the Triumph, and superior in construction and durability. There will be no risk of suit for infringement.

The Frue Vanning Machine Company warn the public that they claim and will prove the Triumph machine to be an infringement on patents owned by them.

Protected by patents May 4, 1869, Dec. 22 1874, Sept. 2, 1879, April 27, 1880, March 22, 1881, Feb. 20, 1883, Sept. 18, 1883. Patents applied for.

N. B.—We are and have been ready at any time to make a competitive trial against the Triumph, or any other Concentrator for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

SEND FOR CIRCULAR.

IMPORTANT TO GOLD MINERS! SILVER-PLATED AMALGAMATING PLATES FOR SAVING GOLD

IN QUARTZ, GRAVEL AND PLACER MINING.

Warranted the Best Made, Durable and Satisfactory. Full weight of silver and best quality of plating guaranteed.

BEST SOFT LAKE SUPERIOR COPPER USED.

Old Mining Plates Bought, Replated, or Gold Separated. 3000 Orders filled. References first class. Prices the very lowest. Have received every Medal awarded on the Pacific Coast for Mining Plates.

SAN FRANCISCO GOLD, SILVER and NICKEL PLATING WORKS, 653 & 655 Mission St., San Francisco.

E. G. DENNISTON, Proprietor.

These Plates can also be procured of JOHN TAYLOR & CO., Dealers in Assayers' and Mining Material, 112 to 118 Pine St.

NOTICE.—Mining men are cautioned against purchasing inferior quality of Silver-Plated Mining Plates now being manufactured in this city. There has been a general complaint by purchasers that these plates proved defective in plating and short in weight of silver, assays showing great deficiency in silver guaranteed. Thin, light plating looks the same as heavy, but has no durability. Good plates can be furnished at same price these poor plates cost.

Hot and Cold Baths Free. None but most obliging white labor employed. Free Coach to and from the Hotel.
MONTGOMERY BROS., Proprietors.

HERCULES SLAYING THE GIANTS.

HERCULES POWDER

Derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

HERCULES POWDER will break more rock, is stronger, safer and better than any other explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE

THE CALIFORNIA POWDER WORKS,

MANUFACTURERS OF

This cut represents our

**IMPROVED
HYDRAULIC
MACHINE.**

IT DIFFERS FROM THE OLD STYLE IN HAVING ONLY ONE JOINT instead of two. It is of greater capacity and more easily worked and kept in repair. The statement of Mr. Hendy that all styles are infringements on this machine made by him, he knows to be utterly false. All litigation has been in reference to old style two jointed machines, which are superseded by our new style one jointed. The decision of Judge Sawyer, referred to by him, is carried up on appeal to U. S. Supreme Court, with absolute certainty of a reversal in our favor. Send for Circulars and Price List. HOSKIN & CO., Marysville, Cal.

IMPROVED FORM OF HYDRAULIC GIANTS.

The above cut illustrates the IMPROVED FORM OF HYDRAULIC GIANTS, which we manufacture. All similar styles are infringements upon this form, and a judgment stands of record to that effect, under the decision of Judge Sawyer of the U. S. Circuit Court in the matter of Hendy and Fisher vs. R. Hoskin et al.

HOOD'S FOUNDRY COKE.

Consumers are respectfully informed that owing to inferior brands of Coke having been sold in this and other countries under the name of "Patent Coke," the Glamorgan Coal Co. (Limited), Cardiff, in May, 1884, abandoned the title of "Patent Foundry Coke," substituting that of "Hood's Foundry Coke."

This Coke is exclusively used by the Selby Smelting and Lead Co., Union Iron Works, Professor Thomas Price, and other consumers here. Large quantities are regularly forwarded to Copper Smelters in Arizona and New Mexico, and also to consumers in Nevada and Salt Lake.

The undersigned are the SOLE IMPORTERS of the above Coke, which is for sale in quantities to suit purchasers.

FULTON IRON WORKS, S. F.

MANUFACTURED BY

HINCKLEY, SPIERS & HAYES,

THE ROLLER ORE FEEDER

[Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar or repairs.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over
other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take the n off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impos-
sible to make them tight except by regrinding, which is expensive if done by hand, and if don-
by machine soon wears out the valve, and in most cases they have to be dis- connected from
the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is
manufactured under our 1886 Patent, and will stand 200 lbs. steam. Sample orders solicited.
To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by
